This course will teach you the basics of the Ada programming language and is intended for those who already have a basic understanding of programming techniques. You will learn how to apply those techniques to programming in Ada.

This document was written by Raphaël Amiard and Gustavo A. Hoffmann, with review from Richard Kenner.

Note: The code examples in this course use a 50-column limit, which greatly improves the readability of the code on devices with a small screen size. This constraint, however, leads to an unusual coding style. For instance, instead of calling Put_Line in a single line, we have this:

```ada
Put_Line (" is in the northeast quadrant");
```

or this:

```ada
Put_Line (" (X => ",
   Integer'Image (P.X)
   
   ");
```

Note that typical Ada code uses a limit of at least 79 columns. Therefore, please don’t take the coding style from this course as a reference!

Note: Each code example from this book has an associated "code block metadata", which contains the name of the "project" and an MD5 hash value. This information is used to identify a single code example.

You can find all code examples in a zip file, which you can download from the learn website\(^2\). The directory structure in the zip file is based on the code block metadata. For example, if you're searching for a code example with this metadata:

- Project: Courses.Intro_To_Ada.Imperative_Language.Greet
- MD5: cba89a34b87c9dfa71533d982d05e6ab

you will find it in this directory:

`projects/Courses/Intro_To_Ada/Imperative_Language/Greet/cba89a34b87c9dfa71533d982d05e6ab/`

\(^1\) [http://creativecommons.org/licenses/by-sa/4.0](http://creativecommons.org/licenses/by-sa/4.0)

\(^2\) [https://learn.adacore.com/zip/learning-ada_code.zip](https://learn.adacore.com/zip/learning-ada_code.zip)
In order to use this code example, just follow these steps:

1. Unpack the zip file;
2. Go to target directory;
3. Start GNAT Studio on this directory;
4. Build (or compile) the project;
5. Run the application (if a main procedure is available in the project).
1.1 History

In the 1970s the United States Department of Defense (DOD) suffered from an explosion of the number of programming languages, with different projects using different and non-standard dialects or language subsets / supersets. The DOD decided to solve this problem by issuing a request for proposals for a common, modern programming language. The winning proposal was one submitted by Jean Ichbiah from CII Honeywell-Bull.

The first Ada standard was issued in 1983; it was subsequently revised and enhanced in 1995, 2005 and 2012, with each revision bringing useful new features.

This tutorial will focus on Ada 2012 as a whole, rather than teaching different versions of the language.

1.2 Ada today

Today, Ada is heavily used in embedded real-time systems, many of which are safety critical. While Ada is and can be used as a general-purpose language, it will really shine in low-level applications:

- Embedded systems with low memory requirements (no garbage collector allowed).
- Direct interfacing with hardware.
- Soft or hard real-time systems.
- Low-level systems programming.

Specific domains seeing Ada usage include Aerospace & Defense, civil aviation, rail, and many others. These applications require a high degree of safety: a software defect is not just an annoyance, but may have severe consequences. Ada provides safety features that detect defects at an early stage — usually at compilation time or using static analysis tools. Ada can also be used to create applications in a variety of other areas, such as:

- Video game programming³
- Real-time audio⁴
- Kernel modules⁵

This is a non-comprehensive list that hopefully sheds light on which kind of programming Ada is good at.

---

³ https://github.com/AdaDoom3/AdaDoom3
⁴ http://www.electronicdesign.com/embedded-revolution/assessing-ada-language-audio-applications
⁵ http://www.nihamkin.com/tag/kernel.html
In terms of modern languages, the closest in terms of targets and level of abstraction are probably C++\textsuperscript{6} and Rust\textsuperscript{7}.

### 1.3 Philosophy

Ada’s philosophy is different from most other languages. Underlying Ada’s design are principles that include the following:

- **Readability is more important than conciseness.** Syntactically this shows through the fact that keywords are preferred to symbols, that no keyword is an abbreviation, etc.

- **Very strong typing.** It is very easy to introduce new types in Ada, with the benefit of preventing data usage errors.
  - It is similar to many functional languages in that regard, except that the programmer has to be much more explicit about typing in Ada, because there is almost no type inference.

- **Explicit is better than implicit.** Although this is a Python\textsuperscript{8} commandment, Ada takes it way further than any language we know of:
  - There is mostly no structural typing, and most types need to be explicitly named by the programmer.
  - As previously said, there is mostly no type inference.
  - Semantics are very well defined, and undefined behavior is limited to an absolute minimum.
  - The programmer can generally give a lot of information about what their program means to the compiler (and other programmers). This allows the compiler to be extremely helpful (read: strict) with the programmer.

During this course, we will explain the individual language features that are building blocks for that philosophy.

### 1.4 SPARK

While this class is solely about the Ada language, it is worth mentioning that another language, extremely close to and interoperable with Ada, exists: the SPARK language.

SPARK is a subset of Ada, designed so that the code written in SPARK is amenable to automatic proof. This provides a level of assurance with regard to the correctness of your code that is much higher than with a regular programming language.

There is a dedicated course for the SPARK language but keep in mind that every time we speak about the specification power of Ada during this course, it is power that you can leverage in SPARK to help proving the correctness of program properties ranging from absence of run-time errors to compliance with formally specified functional requirements.

---

\textsuperscript{6} https://en.wikipedia.org/wiki/C%2B%2B  
\textsuperscript{7} https://www.rust-lang.org/en-US/  
\textsuperscript{8} https://www.python.org
Ada is a multi-paradigm language with support for object orientation and some elements of functional programming, but its core is a simple, coherent procedural/imperative language akin to C or Pascal.

In other languages

One important distinction between Ada and a language like C is that statements and expressions are very clearly distinguished. In Ada, if you try to use an expression where a statement is required then your program will fail to compile. This rule supports a useful stylistic principle: expressions are intended to deliver values, not to have side effects. It can also prevent some programming errors, such as mistakenly using the equality operator \( = \) instead of the assignment operation \( := \) in an assignment statement.

2.1 Hello world

Here's a very simple imperative Ada program:

```ada
with Ada.Text_IO;

procedure Greet
is
begin
   -- Print "Hello, World!" to the screen
   Ada.Text_IO.Put_Line ("Hello, World!");
end Greet;
```

which we'll assume is in the source file `greet.adb`.

There are several noteworthy things in the above program:

- A subprogram in Ada can be either a procedure or a function. A procedure, as illustrated above, does not return a value when called.

- `with` is used to reference external modules that are needed in the procedure. This is similar to `import` in various languages or roughly similar to `#include` in C and C++.
We'll see later how they work in detail. Here, we are requesting a standard library module, the Ada.Text_IO package, which contains a procedure to print text on the screen: Put_Line.

- Greet is a procedure, and the main entry point for our first program. Unlike in C or C++, it can be named anything you prefer. The builder will determine the entry point. In our simple example, gprbuild, GNAT's builder, will use the file you passed as parameter.

- Put_Line is a procedure, just like Greet, except it is declared in the Ada.Text_IO module. It is the Ada equivalent of C's printf.

- Comments start with -- and go to the end of the line. There is no multi-line comment syntax, that is, it is not possible to start a comment in one line and continue it in the next line. The only way to create multiple lines of comments in Ada is by using -- on each line. For example:

  -- We start a comment in this line...
  -- and we continue on the second line...

In other languages

Procedures are similar to functions in C or C++ that return void. We'll see later how to declare functions in Ada.

Here is a minor variant of the "Hello, World" example:

Listing 2: greet.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
   begin
      -- Print "Hello, World!" to the screen
      Put_Line ("Hello, World");
   end Greet;
```

Code block metadata

Project: Courses.Intro_To_Ada.Imperative_Language.Greet_2
MD5: a58a1193207df44aa6edaa4fe1c14280

Runtime output

Hello, World!

This version utilizes an Ada feature known as a use clause, which has the form use package-name. As illustrated by the call on Put_Line, the effect is that entities from the named package can be referenced directly, without the package-name.prefix.
2.2 Imperative language - If/Then/Else

This section describes Ada’s if statement and introduces several other fundamental language facilities including integer I/O, data declarations, and subprogram parameter modes. Ada’s if statement is pretty unsurprising in form and function:

Listing 3: check_positive.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Integer_Text_IO; use Ada.Integer_Text_IO;

procedure Check_Positive is
    N : Integer;
begin
    -- Put a String
    Put ("Enter an integer value: ");
    -- Read in an integer value
    Get (N);
    if N > 0 then
        -- Put an Integer
        Put (N);
        Put_Line (" is a positive number");
    end if;
end Check_Positive;
```

Code block metadata

Project: Courses.Intro.To_Ada.Imperative.Language.Check_Positive
MD5: 2e8b4b2f3f258fd9e02c2d65846af101

The if statement minimally consists of the reserved word if, a condition (which must be a Boolean value), the reserved word then and a non-empty sequence of statements (the then part) which is executed if the condition evaluates to True, and a terminating end if.

This example declares an integer variable N, prompts the user for an integer, checks if the value is positive and, if so, displays the integer's value followed by the string " is a positive number". If the value is not positive, the procedure does not display any output.

The type Integer is a predefined signed type, and its range depends on the computer architecture. On typical current processors Integer is 32-bit signed.

The example illustrates some of the basic functionality for integer input-output. The relevant subprograms are in the predefined package Ada.Integer_Text_IO and include the Get procedure (which reads in a number from the keyboard) and the Put procedure (which displays an integer value).

Here’s a slight variation on the example, which illustrates an if statement with an else part:

Listing 4: check_positive.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Integer_Text_IO; use Ada.Integer_Text_IO;

procedure Check_Positive is
    N : Integer;
begin
    -- Put a String
    Put ("Enter an integer value: ");
(continues on next page)```
-- Reads in an integer value
Get (N);

-- Put an Integer
Put (N);

if N > 0 then
  Put_Line (" is a positive number");
else
  Put_Line (" is not a positive number");
end if;
end Check_Positive;

Code block metadata
Project: Courses.Intro_To_Ada.Imperative_Language.Check_Positive_2
MD5: 28fca0d7840d06d478e5933e8182d1db

In this example, if the input value is not positive then the program displays the value followed by the String " is not a positive number".

Our final variation illustrates an if statement with elsif sections:

Listing 5: check_direction.adb

with Ada.Text_IO; use Ada.Text_IO;
with Ada.Integer_Text_IO; use Ada.Integer_Text_IO;

procedure Check_Direction is
  N : Integer;
beg
  Put ("Enter an integer value: ");
  Get (N);
  Put (N);

  if N = 0 or N = 360 then
    Put_Line (" is due north");
  elsif N in 1 .. 89 then
    Put_Line (" is in the northeast quadrant");
  elsif N = 90 then
    Put_Line (" is due east");
  elsif N in 91 .. 179 then
    Put_Line (" is in the southeast quadrant");
  elsif N = 180 then
    Put_Line (" is due south");
  elsif N in 181 .. 269 then
    Put_Line (" is in the southwest quadrant");
  elsif N = 270 then
    Put_Line (" is due west");
  elsif N in 271 .. 359 then
    Put_Line (" is in the northwest quadrant");
  else
    Put_Line (" is not in the range 0..360");
  end if;
end Check_Direction;

Code block metadata
Project: Courses.Intro_To_Ada.Imperative_Language.Check_Direction
MD5: 7759d30c9bb0bfb88efdf12128f9c382
This example expects the user to input an integer between 0 and 360 inclusive, and displays which quadrant or axis the value corresponds to. The `in` operator in Ada tests whether a scalar value is within a specified range and returns a Boolean result. The effect of the program should be self-explanatory; later we’ll see an alternative and more efficient style to accomplish the same effect, through a `case` statement.

Ada's `elsif` keyword differs from C or C++, where nested `else .. if` blocks would be used instead. And another difference is the presence of the `end if` in Ada, which avoids the problem known as the "dangling else".

### 2.3 Imperative language - Loops

Ada has three ways of specifying loops. They differ from the C / Java / Javascript for-loop, however, with simpler syntax and semantics in line with Ada's philosophy.

#### 2.3.1 For loops

The first kind of loop is the `for` loop, which allows iteration through a discrete range.

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet_5a is
begin
  for I in 1 .. 5 loop
    -- Put_Line is a procedure call
    Put_Line ("Hello, World!" & Integer'Image (I));
    -- ^ Procedure parameter
  end loop;
end Greet_5a;
```

A few things to note:

- `1 .. 5` is a discrete range, from 1 to 5 inclusive.
- The loop parameter `I` (the name is arbitrary) in the body of the loop has a value within this range.
- `I` is local to the loop, so you cannot refer to `I` outside the loop.
- Although the value of `I` is incremented at each iteration, from the program's perspective it is constant. An attempt to modify its value is illegal; the compiler would reject the program.
• **Integer'Image** is a function that takes an Integer and converts it to a **String**. It is an example of a language construct known as an **attribute**, indicated by the ' syntax, which will be covered in more detail later.

• The & symbol is the concatenation operator for String values

• The **end loop** marks the end of the loop

The "step" of the loop is limited to 1 (forward direction) and -1 (backward). To iterate backwards over a range, use the **reverse** keyword:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet_5a_Reverse is
begin
  for I in reverse 1 .. 5 loop
    Put_Line ("Hello, World!" & Integer'Image (I));
  end loop;
end Greet_5a_Reverse;
```

**Runtime output**

Hello, World! 5
Hello, World! 4
Hello, World! 3
Hello, World! 2
Hello, World! 1

The bounds of a **for** loop may be computed at run-time; they are evaluated once, before the loop body is executed. If the value of the upper bound is less than the value of the lower bound, then the loop is not executed at all. This is the case also for **reverse** loops. Thus no output is produced in the following example:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet_No_Op is
begin
  for I in reverse 5 .. 1 loop
    Put_Line ("Hello, World!" & Integer'Image (I));
  end loop;
end Greet_No_Op;
```

**Runtime output**
greet_no_op.adb:5:23: warning: loop range is null, loop will not execute [enabled, by default]

The **for** loop is more general than what we illustrated here; more on that later.
2.3.2 Bare loops

The simplest loop in Ada is the bare loop, which forms the foundation of the other kinds of Ada loops.

Listing 9: greet_5b.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet_5b is
  -- Variable declaration:
  I : Integer := 1;
  -- ^ Type
  -- ^ Initial value
  begin
    loop
      Put_Line ("Hello, World!" & Integer'Image (I));
      -- Exit statement:
      exit when I = 5;
      -- ^ Boolean condition
      -- Assignment:
      I := I + 1;
      -- There is no I++ short form to
      -- increment a variable
    end loop;
  end Greet_5b;
```

This example has the same effect as Greet_5a shown earlier.

It illustrates several concepts:

- We have declared a variable named I between the is and the begin. This constitutes a declarative region. Ada clearly separates the declarative region from the statement part of a subprogram. A declaration can appear in a declarative region but is not allowed as a statement.

- The bare loop statement is introduced by the keyword loop on its own and, like every kind of loop statement, is terminated by the combination of keywords end loop. On its own, it is an infinite loop. You can break out of it with an exit statement.

- The syntax for assignment is :=, and the one for equality is =. There is no way to confuse them, because as previously noted, in Ada, statements and expressions are distinct, and expressions are not valid statements.
2.3.3 While loops

The last kind of loop in Ada is the while loop.

Listing 10: greet_5c.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet_5c is
   I : Integer := 1;
begin
   -- Condition must be a Boolean value
   -- (no Integers).
   -- Operator "<=" returns a Boolean
   while I <= 5 loop
      Put_Line ("Hello, World!" & Integer'Image (I));
      I := I + 1;
   end loop;
end Greet_5c;
```

Code block metadata

Project: Courses.Intro_To_Ada.Imperative_Language.Greet_5c
MD5: 5d1d099477795b226db43736c2810274

Runtime output

Hello, World! 1
Hello, World! 2
Hello, World! 3
Hello, World! 4
Hello, World! 5

The condition is evaluated before each iteration. If the result is false, then the loop is terminated.

This program has the same effect as the previous examples.

In other languages

Note that Ada has different semantics than C-based languages with respect to the condition in a while loop. In Ada the condition has to be a Boolean value or the compiler will reject the program; the condition is not an integer that is treated as either True or False depending on whether it is non-zero or zero.

2.4 Imperative language - Case statement

Ada's case statement is similar to the C and C++ switch statement, but with some important differences.

Here's an example, a variation of a program that was shown earlier with an if statement:

Listing 11: check_direction.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Integer_Text_IO; use Ada.Integer_Text_IO;
```
procedure Check_Direction is  
   N : Integer;  
begin  
   loop  
      Put ("Enter an integer value: ");  
      Get (N);  
      Put (N);  
      case N is  
      when 0 | 360 =>  
         Put_Line (" is due north");  
      when 1 .. 89 =>  
         Put_Line (" is in the northeast quadrant");  
      when 90 =>  
         Put_Line (" is due east");  
      when 91 .. 179 =>  
         Put_Line (" is in the southeast quadrant");  
      when 180 =>  
         Put_Line (" is due south");  
      when 181 .. 269 =>  
         Put_Line (" is in the southwest quadrant");  
      when 270 =>  
         Put_Line (" is due west");  
      when 271 .. 359 =>  
         Put_Line (" is in the northwest quadrant");  
      when others =>  
         Put_Line (" Au revoir");  
      exit;  
   end case;  
   end loop;  
end Check_Direction;

This program repeatedly prompts for an integer value and then, if the value is in the range 0 .. 360, displays the associated quadrant or axis. If the value is an Integer outside this range, the loop (and the program) terminate after outputting a farewell message.

The effect of the case statement is similar to the if statement in an earlier example, but the case statement can be more efficient because it does not involve multiple range tests.

Notable points about Ada's case statement:

- The case expression (here the variable N) must be of a discrete type, i.e. either an integer type or an enumeration type. Discrete types will be covered in more detail later discrete types (page 43).
- Every possible value for the case expression needs to be covered by a unique branch of the case statement. This will be checked at compile time.
Introduction to Ada

• A branch can specify a single value, such as 0; a range of values, such as 1 .. 89; or any combination of the two (separated by a |).
• As a special case, an optional final branch can specify others, which covers all values not included in the earlier branches.
• Execution consists of the evaluation of the case expression and then a transfer of control to the statement sequence in the unique branch that covers that value.
• When execution of the statements in the selected branch has completed, control resumes after the end case. Unlike C, execution does not fall through to the next branch. So Ada doesn't need (and doesn't have) a break statement.

2.5 Imperative language - Declarative regions

As mentioned earlier, Ada draws a clear syntactic separation between declarations, which introduce names for entities that will be used in the program, and statements, which perform the processing. The areas in the program where declarations may appear are known as declarative regions.

In any subprogram, the section between the is and the begin is a declarative region. You can have variables, constants, types, inner subprograms, and other entities there.

We’ve briefly mentioned variable declarations in previous subsection. Let’s look at a simple example, where we declare an integer variable X in the declarative region and perform an initialization and an addition on it:

Listing 12: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
procedure Main is
  X : Integer;
begin
  X := 0;
  Put_Line ("The initial value of X is " & Integer'Image (X));
  Put_Line ("Performing operation on X...");
  X := X + 1;
  Put_Line ("The value of X now is " & Integer'Image (X));
end Main;
```

Code block metadata

Project: Courses.Intro_To_Ada.Imperative_Language.Variable_Declaration
MD5: cbb08d5e382fbfccc28e986bea0cd253

Runtime output

The initial value of X is 0
Performing operation on X...
The value of X now is 1

Let's look at an example of a nested procedure:
Listing 13: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
    procedure Nested is
        begin
            Put_Line ("Hello World");
        end Nested;
    begin
        Nested;
        -- Call to Nested
    end Main;
```

Code block metadata

Project: Courses.Intro_To_Ada.Imperative_Language.Nested_Procedure
MD5: 2e7fb267e31232196065febd5e35e6ef

Runtime output

Hello World

A declaration cannot appear as a statement. If you need to declare a local variable amidst the statements, you can introduce a new declarative region with a block statement:

Listing 14: greet.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
    begin
        loop
            Put_Line ("Please enter your name: ");

            declare
            Name : String := Get_Line;
            -- ^ Call to the Get_Line function
            begin
                exit when Name = "";
                Put_Line ("Hi " & Name & "!");
            end;
            -- Name is undefined here
            end loop;
        Put_Line ("Bye!");
    end Greet;
```

Code block metadata

Project: Courses.Intro_To_Ada.Imperative_Language.Greet_6
MD5: a9c0c14a1b3e2ebe07cd88f442787e3a

Attention: The Get_Line function allows you to receive input from the user, and get the result as a string. It is more or less equivalent to the scanf C function. It returns a String, which, as we will see later, is an Unconstrained array type (page 74). For now we simply note that, if you wish to declare a String variable and do not know

2.5. Imperative language - Declarative regions
its size in advance, then you need to initialize the variable during its declaration.

2.6 Imperative language - conditional expressions

Ada 2012 introduced an expression analog for conditional statements (if and case).

2.6.1 If expressions

Here's an alternative version of an example we saw earlier; the if statement has been replaced by an if expression:

Listing 15: check_positive.adb

```
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Integer_Text_IO; use Ada.Integer_Text_IO;

procedure Check_Positive is
  N : Integer;
begin
  Put ("Enter an integer value: ");
  Get (N);
  Put (N);
  declare
  S : constant String :=
    (if N > 0
      then " is a positive number"
      else " is not a positive number"
    ) begin
    Put_Line (S);
  end;
  end Check_Positive;
```

The if expression evaluates to one of the two Strings depending on N, and assigns that value to the local variable S.

Ada's if expressions are similar to if statements. However, there are a few differences that stem from the fact that it is an expression:

- All branches' expressions must be of the same type
- It must be surrounded by parentheses if the surrounding expression does not already contain them
- An else branch is mandatory unless the expression following then has a Boolean value. In that case an else branch is optional and, if not present, defaults to else True.

Here's another example:
Listing 16: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
begin
for I in 1 .. 10 loop
  Put_Line (if I mod 2 = 0 then "Even" else "Odd");
end loop;
end Main;
```

This program produces 10 lines of output, alternating between "Odd" and "Even".

### 2.6.2 Case expressions

Analogous to if expressions, Ada also has case expressions. They work just as you would expect.

Listing 17: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
begin
for I in 1 .. 10 loop
  Put_Line (case I is
    when 1 | 3 | 5 | 7 | 9 => "Odd",
               when 2 | 4 | 6 | 8 | 10 => "Even");
end loop;
end Main;
```

This program produces 10 lines of output, alternating between "Odd" and "Even".

2.6. Imperative language - conditional expressions
This program has the same effect as the preceding example.

The syntax differs from case statements, with branches separated by commas.
3.1 Subprograms

So far, we have used procedures, mostly to have a main body of code to execute. Procedures are one kind of subprogram.

There are two kinds of subprograms in Ada, functions and procedures. The distinction between the two is that a function returns a value, and a procedure does not.

This example shows the declaration and definition of a function:

Listing 1: increment.ads

```ada
function Increment (I : Integer) return Integer;
```

Listing 2: increment.adb

```ada
-- We declare (but don't define) a function with
-- one parameter, returning an integer value

function Increment (I : Integer) return Integer is
  -- We define the Increment function
  begin
    return I + 1;
  end Increment;
```

Subprograms in Ada can, of course, have parameters. One syntactically important note is that a subprogram which has no parameters does not have a parameter section at all, for example:

```ada
procedure Proc;
function Func return Integer;
```

Here's another variation on the previous example:

Listing 3: increment_by.ads

```ada
function Increment_By
  (I : Integer := 0;
   Incr : Integer := 1) return Integer;
  ^ Default value for parameters
```
In this example, we see that parameters can have default values. When calling the subprogram, you can then omit parameters if they have a default value. Unlike C/C++, a call to a subprogram without parameters does not include parentheses.

This is the implementation of the function above:

```ada
function Increment_By (I : Integer := 0; Incr : Integer := 1) return Integer is
begin
  return I + Incr;
end Increment_By;
```

In the GNAT toolchain

The Ada standard doesn't mandate in which file the specification or the implementation of a subprogram must be stored. In other words, the standard doesn't require a specific file structure or specific file name extensions. For example, we could save both the specification and the implementation of the `Increment` function above in a file called `increment.txt`. (We could even store the entire source code of a system in a single file.) From the standard's perspective, this would be completely acceptable.

The GNAT toolchain, however, requires the following file naming scheme:

- files with the `.ads` extension contain the specification, while
- files with the `.adb` extension contain the implementation.

Therefore, in the GNAT toolchain, the specification of the `Increment` function must be stored in the `increment.ads` file, while its implementation must be stored in the `increment.adb` file. This rule always applies to packages, which we discuss later (page 31). (Note, however, that it's possible to circumvent this rule.) For more details, you may refer to the Introduction to GNAT Toolchain course or the GPRbuild User's Guide.

### 3.1.1 Subprogram calls

We can then call our subprogram this way:

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Increment_By;

procedure Show_Increment is
  A, B, C : Integer;
begin
  C := Increment_By;
end Show_Increment;
```

---

-- Parameterless call,
-- value of I is 0
-- and Incr is 1

Put_Line ("Using defaults for Increment_By is 
  & Integer'Image (C));

A := 10;
B := 3;
C := Increment_By (A, B);

-- Regular parameter passing

Put_Line ("Increment of 
  & Integer'Image (A) 
  & " with 
  & Integer'Image (B) 
  & " is 
  & Integer'Image (C));

A := 20;
B := 5;
C := Increment_By (I => A, 
                   Incr => B);

-- Named parameter passing

Put_Line ("Increment of 
  & Integer'Image (A) 
  & " with 
  & Integer'Image (B) 
  & " is 
  & Integer'Image (C));

end Show_Increment;

Ada allows you to name the parameters when you pass them, whether they have a default or not. There are some rules:

- Positional parameters come first.
- A positional parameter cannot follow a named parameter.

As a convention, people usually name parameters at the call site if the function's corresponding parameters has a default value. However, it is also perfectly acceptable to name every parameter if it makes the code clearer.
3.1.2 Nested subprograms

As briefly mentioned earlier, Ada allows you to declare one subprogram inside another. This is useful for two reasons:

- It lets you organize your programs in a cleaner fashion. If you need a subprogram only as a "helper" for another subprogram, then the principle of localization indicates that the helper subprogram should be declared nested.
- It allows you to share state easily in a controlled fashion, because the nested subprograms have access to the parameters, as well as any local variables, declared in the outer scope.

For the previous example, we can move the duplicated code (call to Put_Line) to a separate procedure. This is a shortened version with the nested Display_Result procedure.

```
with Ada.Text_IO; use Ada.Text_IO;
with Increment_By;

procedure Show_Increment is
  A, B, C : Integer;

procedure Display_Result is
begin
  Put_Line ("Increment of ",
            Integer'Image (A),
            " with ",
            Integer'Image (B),
            " is ",
            Integer'Image (C));
end Display_Result;

begin
  A := 10;
  B := 3;
  C := Increment_By (A, B);
  Display_Result;
  A := 20;
  B := 5;
  C := Increment_By (A, B);
  Display_Result;
end Show_Increment;
```

Code block metadata

Project: Courses.Intro_To_Ada.Subprograms.Increment_By
MD5: 23ec8ae30880c042123a9e82ee6b3d9e3

Runtime output

Increment of 10 with 3 is 13
Increment of 20 with 5 is 25
3.1.3 Function calls

An important feature of function calls in Ada is that the return value at a call cannot be ignored; that is, a function call cannot be used as a statement.

If you want to call a function and do not need its result, you will still need to explicitly store it in a local variable.

Listing 7: quadruple.adb

```ada
function Quadruple (I : Integer)
  return Integer is

function Double (I : Integer)
  return Integer is
begin
  return I * 2;
end Double;

Res : Integer := Double (Double (I));
-- ^ Calling the Double
-- function
begin
  Double (I);
-- ERROR: cannot use call to function "Double" as a statement
return Res;
end Quadruple;
```

Code block metadata

Project: Courses.Intro_To_Ada.Subprograms.Quadruple
MD5: 44326f12a9d797ea13ffe52ea48fc36f

Build output

quadruple.adb:14:04: error: cannot use call to function "Double" as a statement
quadruple.adb:14:04: error: return value of a function call cannot be ignored

gprbuild: *** compilation phase failed

In the GNAT toolchain

In GNAT, with all warnings activated, it becomes even harder to ignore the result of a function, because unused variables will be flagged. For example, this code would not be valid:

```ada
function Read_Int
  (Stream : Network_Stream;
   Result : out Integer) return Boolean;

procedure Main is
  Stream : Network_Stream := Get_Stream;
  My_Int : Integer;

  -- Warning: in the line below, B is
  -- never read.
  B : Boolean := Read_Int (Stream, My_Int);
begin
  null;
end Main;
```

You then have two solutions to silence this warning:
• Either annotate the variable with \texttt{pragma Unreferenced}, e.g.:

\begin{verbatim}
B : Boolean := Read_Int (Stream, My_Int);
pragma Unreferenced (B);
\end{verbatim}

• Or give the variable a name that contains any of the strings \texttt{discard dummy ignore junk unused} (case insensitive)

\section*{3.2 Parameter modes}

So far we have seen that Ada is a safety-focused language. There are many ways this is realized, but two important points are:

• Ada makes the user specify as much as possible about the behavior expected for the program, so that the compiler can warn or reject if there is an inconsistency.

• Ada provides a variety of techniques for achieving the generality and flexibility of pointers and dynamic memory management, but without the latter's drawbacks (such as memory leakage and dangling references).

Parameter modes are a feature that helps achieve the two design goals above. A subprogram parameter can be specified with a mode, which is one of the following:

\begin{center}
\begin{tabular}{l|l}
\hline
\texttt{in} & Parameter can only be read, not written \\
\texttt{out} & Parameter can be written to, then read \\
\texttt{in out} & Parameter can be both read and written \\
\hline
\end{tabular}
\end{center}

The default mode for parameters is \texttt{in}; so far, most of the examples have been using \texttt{in} parameters.

\section*{Historically}

Functions and procedures were originally more different in philosophy. Before Ada 2012, functions could only take \texttt{in} parameters.

\section*{3.3 Subprogram calls}

\subsection*{3.3.1 In parameters}

The first mode for parameters is the one we have been implicitly using so far. Parameters passed using this mode cannot be modified, so that the following program will cause an error:

\begin{verbatim}
procedure Swap (A, B : Integer) is
    Tmp : Integer;
begin
    Tmp := A;
-- Error: assignment to "in" mode
-- parameter not allowed
\end{verbatim}

(continues on next page)
A := B;  

-- Error: assignment to "in" mode  
-- parameter not allowed  
B := Tmp;  
end Swap;  

Code block metadata

Project: Courses.Intro_To_Ada.Subprograms.Swap  
MD5: 478ac23f878934aae820e4b9c056d939  

Build output

swap.adb:8:04: error: assignment to "in" mode parameter not allowed  
swap.adb:12:04: error: assignment to "in" mode parameter not allowed  
gprbuild: *** compilation phase failed  

The fact that in is the default mode is very important. It means that a parameter will not be modified unless you explicitly specify a mode in which modification is allowed.

3.3.2 In out parameters

To correct our code above, we can use an in out parameter.

Listing 9: in_out_params.adb

with Ada.Text_IO; use Ada.Text_IO;  
procedure In_Out_Params is  
  procedure Swap (A, B : in out Integer) is  
    Tmp : Integer;  
  begin  
    Tmp := A;  
    A := B;  
    B := Tmp;  
  end Swap;  
begin  
  A := Integer := 12;  
  B := Integer := 44;  
begin  
  Swap (A, B);  
  -- Prints 44  
  Put_Line (Integer'Image (A));  
end In_Out_Params;  

Code block metadata

Project: Courses.Intro_To_Ada.Subprograms.In_Out_Params  
MD5: 319358e479449c115cf2b3cbb4ff3a6b  

Runtime output

44  

An in out parameter will allow read and write access to the object passed as parameter, so in the example above, we can see that A is modified after the call to Swap.

3.3. Subprogram calls
Introduction to Ada

**Attention:** While in out parameters look a bit like references in C++, or regular parameters in Java that are passed by-reference, the Ada language standard does not mandate "by reference" passing for in out parameters except for certain categories of types as will be explained later.

In general, it is better to think of modes as higher level than by-value versus by-reference semantics. For the compiler, it means that an array passed as an in parameter might be passed by reference, because it is more efficient (which does not change anything for the user since the parameter is not assignable). However, a parameter of a discrete type will always be passed by copy, regardless of its mode (which is more efficient on most architectures).

### 3.3.3 Out parameters

The out mode applies when the subprogram needs to write to a parameter that might be uninitialized at the point of call. Reading the value of an out parameter is permitted, but it should only be done after the subprogram has assigned a value to the parameter. Out parameters behave a bit like return values for functions. When the subprogram returns, the actual parameter (a variable) will have the value of the out parameter at the point of return.

**In other languages**

Ada doesn't have a tuple construct and does not allow returning multiple values from a subprogram (except by declaring a full-fledged record type). Hence, a way to return multiple values from a subprogram is to use out parameters.

For example, a procedure reading integers from the network could have one of the following specifications:

```ada
procedure Read_Int
(  Stream : Network_Stream;
  Success : out Boolean;
  Result : out Integer);

function Read_Int
(  Stream : Network_Stream;
  Result : out Integer) return Boolean;
```

While reading an out variable before writing to it should, ideally, trigger an error, imposing that as a rule would cause either inefficient run-time checks or complex compile-time rules. So from the user's perspective an out parameter acts like an uninitialized variable when the subprogram is invoked.

**In the GNAT toolchain**

GNAT will detect simple cases of incorrect use of out parameters. For example, the compiler will emit a warning for the following program:

```ada
procedure Outp is
  procedure Foo (A : out Integer) is
    B : Integer := A;
    -- ^ Warning on reference
    -- to uninitialized A
```

(continues on next page)
3.3.4 Forward declaration of subprograms

As we saw earlier, a subprogram can be declared without being fully defined. This is possible in general, and can be useful if you need subprograms to be mutually recursive, as in the example below:

Listing 11: mutually_recursive_subprograms.adb

```ada
procedure Mutually_Recursive_Subprograms is
  procedure Compute_A (V : Natural);  -- Forward declaration of Compute_A
  procedure Compute_B (V : Natural) is
    begin
      if V > 5 then
        Compute_A (V - 1);  -- Call to Compute_A
      end if;
    end Compute_B;
  procedure Compute_A (V : Natural) is
    begin
      if V > 2 then
        Compute_B (V - 1);  -- Call to Compute_B
      end if;
    end Compute_A;
  begin
    Compute_A (15);
  end Mutually_Recursive_Subprograms;
```

Code block metadata

Project: Courses.Intro_To_Ada.Subprograms.Mutually_Recursive_Subprograms
MD5: 5ee030cdecc6c4aea8916cbb763e8526

3.3. Subprogram calls
3.4 Renaming

Subprograms can be renamed by using the `renames` keyword and declaring a new name for a subprogram:

```ada
procedure New_Proc renames Original_Proc;
```

This can be useful, for example, to improve the readability of your application when you're using code from external sources that cannot be changed in your system. Let's look at an example:

Listing 12: a_procedure_with_very_long_name_that_cannot_be_changed.ads

```ada
procedure A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed
  (A_Message : String);
```

Listing 13: a_procedure_with_very_long_name_that_cannot_be_changed.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed
  (A_Message : String) is
begin
  Put_Line (A_Message);
end A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed;
```

As the wording in the name of procedure above implies, we cannot change its name. We can, however, rename it to something like `Show` in our test application and use this shorter name. Note that we also have to declare all parameters of the original subprogram — we may rename them, too, in the declaration. For example:

Listing 14: show_renaming.adb

```ada
with A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed;

procedure Show_Renaming is
begin
  Show ("Hello World!");
end Show_Renaming;
```

```
```

Note that the original name (`A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed`) is still visible after the declaration of the Show procedure.
We may also rename subprograms from the standard library. For example, we may rename `Integer'Image` to `Img`:

Listing 15: show_image_renaming.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Image_Renaming is

    function Img (I : Integer) return String
        renames Integer'Image;

begin
    Put_Line (Img (2));
    Put_Line (Img (3));
end Show_Image_Renaming;
```

Renaming also allows us to introduce default expressions that were not available in the original declaration. For example, we may specify "Hello World!" as the default for the `String` parameter of the `Show` procedure:

```ada
with A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed;

procedure Show_Renaming_Defaults is

    procedure Show (S : String := "Hello World!")
        renames A_Procedure_With_Very_Long_Name_That_Cannot_Be_Changed;

begin
    Show;
end Show_Renaming_Defaults;
```
So far, our examples have been simple standalone subprograms. Ada is helpful in that regard, since it allows arbitrary declarations in a declarative part. We were thus able to declare our types and variables in the bodies of main procedures.

However, it is easy to see that this is not going to scale up for real-world applications. We need a better way to structure our programs into modular and distinct units.

Ada encourages the separation of programs into multiple packages and sub-packages, providing many tools to a programmer on a quest for a perfectly organized code-base.

### 4.1 Packages

Here is an example of a package declaration in Ada:

```ada
package Week is
  Mon : constant String := "Monday";
  Tue : constant String := "Tuesday";
  Wed : constant String := "Wednesday";
  Thu : constant String := "Thursday";
  Fri : constant String := "Friday";
  Sat : constant String := "Saturday";
  Sun : constant String := "Sunday";
end Week;
```

And here is how you use it:

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Week;

procedure Main is
begin
  Put_Line ("First day of the week is ")
```

(continues on next page)
Introduction to Ada

9 | & Week.Mon);
10 | end Main;

Code block metadata

Project: Courses.Intro_To_Ada.Modular_Programming.Week
MD5: 03e17a75620de6a397b1d3c5a3e22f6a

Runtime output

First day of the week is Monday

Packages let you make your code modular, separating your programs into semantically significant units. Additionally the separation of a package's specification from its body (which we will see below) can reduce compilation time.

While the with clause indicates a dependency, you can see in the example above that you still need to prefix the referencing of entities from the Week package by the name of the package. (If we had included a use Week clause, then such a prefix would not have been necessary.)

Accessing entities from a package uses the dot notation, A.B, which is the same notation as the one used to access record fields.

A with clause can only appear in the prelude of a compilation unit (i.e., before the reserved word, such as procedure, that marks the beginning of the unit). It is not allowed anywhere else. This rule is only needed for methodological reasons: the person reading your code should be able to see immediately which units the code depends on.

In other languages

Packages look similar to, but are semantically very different from, header files in C/C++.  

• The first and most important distinction is that packages are a language-level mechanism. This is in contrast to a #include'd header file, which is a functionality of the C preprocessor.

• An immediate consequence is that the with construct is a semantic inclusion mechanism, not a text inclusion mechanism. Hence, when you with a package, you are saying to the compiler "I'm depending on this semantic unit", and not "include this bunch of text in place here".

• The effect of a package thus does not vary depending on where it has been withed from. Contrast this with C/C++, where the meaning of the included text depends on the context in which the #include appears.

This allows compilation/recompilation to be more efficient. It also allows tools like IDEs to have correct information about the semantics of a program. In turn, this allows better tooling in general, and code that is more analyzable, even by humans.

An important benefit of Ada with clauses when compared to #include is that it is stateless. The order of with and use clauses does not matter, and can be changed without side effects.

In the GNAT toolchain

The Ada language standard does not mandate any particular relationship between source files and packages; for example, in theory you can put all your code in one file, or use your own file naming conventions. In practice, however, an implementation will have specific rules. With GNAT, each top-level compilation unit needs to go into a separate file. In the
example above, the Week package will be in an .ads file (for Ada specification), and the Main procedure will be in an .adb file (for Ada body).

### 4.2 Using a package

As we have seen above, the `with` clause indicates a dependency on another package. However, every reference to an entity coming from the Week package had to be prefixed by the full name of the package. It is possible to make every entity of a package visible directly in the current scope, using the `use` clause.

In fact, we have been using the `use` clause since almost the beginning of this tutorial.

Listing 3: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
-- ^ Make every entity of the Ada.Text_IO package directly visible.
with Week;

procedure Main is
  use Week;
  -- Make every entity of the Week package directly visible.
begin
  Put_Line ("First day of the week is " & Mon);
end Main;
```

As you can see in the example above:

- `Put_Line` is a subprogram that comes from the `Ada.Text_IO` package. We can reference it directly because we have `used` the package at the top of the `Main` unit.
- Unlike `with` clauses, a `use` clause can be placed either in the prelude, or in any declarative region. In the latter case the `use` clause will have an effect in its containing lexical scope.

### 4.3 Package body

In the simple example above, the Week package only has declarations and no body. That's not a mistake: in a package specification, which is what is illustrated above, you cannot declare bodies. Those have to be in the package body.
Here we can see that the body of the `Increment_By` function has to be declared in the body. Coincidentally, introducing a body allows us to put the `Last_Increment` variable in the body, and make them inaccessible to the user of the `Operations` package, providing a first form of encapsulation.

This works because entities declared in the body are only visible in the body.

This example shows how `Last_Increment` is used indirectly:

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Operations;

procedure Main is
  use Operations;
  I : Integer := 0;
  R : Integer;
  procedure Display_Update_Values is
  (continues on next page)
```

Code block metadata

MD5: 2adfb64e825605c74fecf6c9d45c8437
### 4.4 Child packages

Packages can be used to create hierarchies. We achieve this by using child packages, which extend the functionality of their parent package. One example of a child package that we've been using so far is the Ada.Text_IO package. Here, the parent package is called Ada, while the child package is called Text_IO. In the previous examples, we've been using the Put_Line procedure from the Text_IO child package.

**Important**

Ada also supports nested packages. However, since they can be more complicated to use, the recommendation is to use child packages instead. Nested packages will be covered in the advanced course.

Let's begin our discussion on child packages by taking our previous Week package:
package Week is

Mon : constant String := "Monday";
Tue : constant String := "Tuesday";
Wed : constant String := "Wednesday";
Thu : constant String := "Thursday";
Fri : constant String := "Friday";
Sat : constant String := "Saturday";
Sun : constant String := "Sunday";

end Week;

Code block metadata

MD5: 0fa033dc8fe2b9741483de273354e7ee

If we want to create a child package for Week, we may write:

package Week.Child is

function Get_First_Of_Week return String;

end Week.Child;

Code block metadata

MD5: a7db38e772cf6153b5eb950695b17e833

Here, Week is the parent package and Child is the child package. This is the corresponding package body of Week.Child:

package body Week.Child is

function Get_First_Of_Week return String is
begin
  return Mon;
end Get_First_Of_Week;

end Week.Child;

Code block metadata

MD5: 04dad82685ad9f0231c3084266b0af83

In the implementation of the Get_First_Of_Week function, we can use the Mon string directly, even though it was declared in the parent package Week. We don't write with Week here because all elements from the specification of the Week package — such as Mon, Tue and so on — are visible in the child package Week.Child.

Now that we've completed the implementation of the Week.Child package, we can use elements from this child package in a subprogram by simply writing with Week.Child. Similarly, if we want to use these elements directly, we write use Week.Child in addition. For example:
Introduction to Ada

Listing 10: main.adb

```ada
with Ada.Text_IO;  use Ada.Text_IO;
with Week.Child;  use Week.Child;

procedure Main is
begin
   Put_Line ("First day of the week is "
              & Get_First_Of_Week);
end Main;
```

Code block metadata

MD5: e2f5c6ad3a92da4cb04ee7ec12293df4

Runtime output

First day of the week is Monday

4.4.1 Child of a child package

So far, we've seen a two-level package hierarchy. But the hierarchy that we can potentially create isn't limited to that. For instance, we could extend the hierarchy of the previous source code example by declaring a `Week.Child.Grandchild` package. In this case, `Week.Child` would be the parent of the Grandchild package. Let's consider this implementation:

Listing 11: week-child-grandchild.ads

```ada
package Week.Child.Grandchild is
   function Get_Second_Of_Week return String;
end Week.Child.Grandchild;
```

Listing 12: week-child-grandchild.adb

```ada
package body Week.Child.Grandchild is
   function Get_Second_Of_Week return String is
      begin
         return Tue;
      end Get_Second_Of_Week;
end Week.Child.Grandchild;
```

Code block metadata

MD5: 03ee5932a68212b2e501370212508ab1

We can use this new Grandchild package in our test application in the same way as before: we can reuse the previous test application and adapt the `with` and `use`, and the function call. This is the updated code:

Listing 13: main.adb

```ada
with Ada.Text_IO;  use Ada.Text_IO;
```

(continues on next page)
with Week.Child.Grandchild;
use Week.Child.Grandchild;

procedure Main is
begin
  Put_Line ("Second day of the week is "
    & Get_Sec""o"
    & Get_Second_Of_Week);
end Main;

4.4.2 Multiple children

So far, we've seen a single child package of a parent package. However, a parent package can also have multiple children. We could extend the example above and implement a Week.Child_2 package. For example:

Listing 14: week-child_2.ads

package Week.Child_2 is

  function Get_Last_Of_Week return String;

end Week.Child_2;

Listing 15: week-child_2.adb

package body Week.Child_2 is

  function Get_Last_Of_Week return String is
    return Sun;
  end Get_Last_Of_Week;

end Week.Child_2;
We can now reference both children in our test application:

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Week.Child; use Week.Child;
with Week.Child_2; use Week.Child_2;

procedure Main is
begin
  Put_Line ("First day of the week is ", Get_First_Of_Week);
  Put_Line ("Last day of the week is ", Get_Last_Of_Week);
end Main;
```

4.4.3 Visibility

In the previous section, we’ve seen that elements declared in a parent package specification are visible in the child package. This is, however, not the case for elements declared in the package body of a parent package.

Let’s consider the package Book and its child Additional_Operations:

```ada
package Book is
  Title : constant String := "Visible for my children";
  function Get_Title return String;
  function Get_Author return String;
end Book;
```

```ada
package Book.Additional_Operations is
  function Get_Extended_Title return String;
  function Get_Extended_Author return String;
end Book.Additional_Operations;
```
This is the body of both packages:

```ada
package body Book is

  Author : constant String :=
    "Author not visible for my children";

  function Get_Title return String is
    begin
      return Title;
    end Get_Title;

  function Get_Author return String is
    begin
      return Author;
    end Get_Author;

end Book;
```

```ada
package body Book.Additional_Operations is

  function Get_Extended_Title return String is
    begin
      return "Book Title: " & Title;
    end Get_Extended_Title;

  function Get_Extended_Author return String is
    begin
      return "Book Author: Unknown";
    end Get_Extended_Author;

end Book.Additional_Operations;
```

In the implementation of the Get_Extended_Title, we're using the Title constant from the parent package Book. However, as indicated in the comments of the Get_Extended_Author function, the Author string — which we declared in the body of the Book package — isn't visible in the Book.Additional_Operations package. Therefore, we cannot use it to implement the Get_Extended_Author function.

We can, however, use the Get_Author function from Book in the implementation of the Get_Extended_Author function to retrieve this string. Likewise, we can use this strategy to implement the Get_Extended_Title function. This is the adapted code:
By declaring elements in the body of a package, we can implement encapsulation in Ada. Those elements will only be visible in the package body, but nowhere else. This isn't, however, the only way to achieve encapsulation in Ada: we'll discuss other approaches in the Privacy (page 109) chapter.
### 4.5 Renaming

Previously, we've mentioned that *subprograms can be renamed* (page 28). We can rename packages, too. Again, we use the `renames` keyword for that. The following example renames the Ada.Text_IO package as TIO:

Listing 23: main.adb

```ada
with Ada.Text_IO;

procedure Main is
   package TIO renames Ada.Text_IO;
begin
   TIO.Put_Line ("Hello");
end Main;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Modular_Programming.Rename_Text_IO

MD5: 33652dd004ef33d95c168ab8893cd412

**Runtime output**

Hello

We can use renaming to improve the readability of our code by using shorter package names. In the example above, we write TIO.Put_Line instead of the longer version (Ada.Text_IO.Put_Line). This approach is especially useful when we don't *use* packages and want to avoid that the code becomes too verbose.

Note we can also rename subprograms and objects inside packages. For instance, we could have just renamed the Put_Line procedure in the source code example above:

Listing 24: main.adb

```ada
with Ada.Text_IO;

procedure Main is
   procedure Say (Something : String)
      renames Ada.Text_IO.Put_Line;
begin
   Say ("Hello");
end Main;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Modular_Programming.Rename_Put_Line

MD5: f30174ff29eb01f33bc95f1787f9f1dc

**Runtime output**

Hello

In this example, we rename the Put_Line procedure to Say.
Ada is a strongly typed language. It is interestingly modern in that respect: strong static typing has been increasing in popularity in programming language design, owing to factors such as the growth of statically typed functional programming, a big push from the research community in the typing domain, and many practical languages with strong type systems.

5.1 What is a type?

In statically typed languages, a type is mainly (but not only) a compile time construct. It is a construct to enforce invariants about the behavior of a program. Invariants are unchangeable properties that hold for all variables of a given type. Enforcing them ensures, for example, that variables of a data type never have invalid values.

A type is used to reason about the objects a program manipulates (an object is a variable or a constant). The aim is to classify objects by what you can accomplish with them (i.e., the operations that are permitted), and this way you can reason about the correctness of the objects’ values.

5.2 Integers

A nice feature of Ada is that you can define your own integer types, based on the requirements of your program (i.e., the range of values that makes sense). In fact, the definitional mechanism that Ada provides forms the semantic basis for the predefined integer types. There is no "magical" built-in type in that regard, which is unlike most languages, and arguably very elegant.

Listing 1: integer_type_example.adb

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Integer_Type_Example is
  -- Declare a signed integer type, and give the bounds
  type My_Int is range -1 .. 20;
  -- ^ High bound
  -- ^ Low bound
  -- Like variables, type declarations can only appear in declarative regions.
begin
  for I in My_Int loop
    Put_Line (My_Int'Image (I));
    -- ^ 'Image attribute
```

(continues on next page)
This example illustrates the declaration of a signed integer type, and several things we can do with them.

Every type declaration in Ada starts with the `type` keyword (except for task types (page 157)). After the type, we can see a range that looks a lot like the ranges that we use in for loops, that defines the low and high bound of the type. Every integer in the inclusive range of the bounds is a valid value for the type.

Ada integer types

In Ada, an integer type is not specified in terms of its machine representation, but rather by its range. The compiler will then choose the most appropriate representation.

Another point to note in the above example is the `My_Int'Image (I)` expression. The `Name'Attribute (optional params)` notation is used for what is called an attribute in Ada. An attribute is a built-in operation on a type, a value, or some other program entity. It is accessed by using a ' symbol (the ASCII apostrophe).

Ada has several types available as "built-ins"; `Integer` is one of them. Here is how `Integer` might be defined for a typical processor:

```ada
type Integer is
  range -(2 ** 31) .. +(2 ** 31 - 1);
```

** is the exponent operator, which means that the first valid value for `Integer` is \(-2^{31}\), and the last valid value is \(2^{31} - 1\).
Ada does not mandate the range of the built-in type `Integer`. An implementation for a 16-bit target would likely choose the range -$2^{15}$ through $2^{15} - 1$.

### 5.2.1 Operational semantics

Unlike some other languages, Ada requires that operations on integers should be checked for overflow.

```ada
procedure Main is
  A : Integer := Integer'Last;
  B : Integer;
begin
  B := A + 5;
  -- This operation will overflow, eg. it
  -- will raise an exception at run time.
end Main;
```

#### Code block metadata

**Project:** Courses.Intro_To_Ada.Strongly_Typed_Language.Overflow_Check  
**MD5:** bddd15b394f0434420248999d12b982f

#### Build output

main.adb:5:11: warning: value not in range of type "Standard.Integer" [enabled by default]  
main.adb:5:11: warning: Constraint_Error will be raised at run time [enabled by default]

#### Runtime output

raised CONSTRAINT_ERROR : main.adb:5 overflow check failed

There are two types of overflow checks:

- Machine-level overflow, when the result of an operation exceeds the maximum value (or is less than the minimum value) that can be represented in the storage reserved for an object of the type, and
- Type-level overflow, when the result of an operation is outside the range defined for the type.

Mainly for efficiency reasons, while machine-level overflow always results in an exception, type-level overflows will only be checked at specific boundaries, like assignment:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
  type My_Int is range 1 .. 20;
  A : My_Int := 12;
  B : My_Int := 15;
  M : My_Int := (A + B) / 2;
  -- No overflow here, overflow checks
  -- are done at specific boundaries.
begin
  for I in 1 .. M loop
```

(continues on next page)
Introduction to Ada

(continued from previous page)

12 | Put_Line ("Hello, World!");
13 | end loop;
14 | -- Loop body executed 13 times
15 | end Main;

Code block metadata

Project: Courses.Intro To Ada.Strongly_Typed_Language.Overflow_Check_2
MD5: d24283cbb42c0be5b5fa215eb16ad2e7

Runtime output

Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!
Hello, World!

Type-level overflow will only be checked at specific points in the execution. The result, as we see above, is that you might have an operation that overflows in an intermediate computation, but no exception will be raised because the final result does not overflow.

5.3 Unsigned types

Ada also features unsigned Integer types. They're called modular types in Ada parlance. The reason for this designation is due to their behavior in case of overflow: They simply "wrap around", as if a modulo operation was applied.

For machine sized modular types, for example a modulus of $2^{32}$, this mimics the most common implementation behavior of unsigned types. However, an advantage of Ada is that the modulus is more general:

Listing 4: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
  type Mod_Int is mod 2 ** 5;
  ^ Range is 0 .. 31
  A : constant Mod_Int := 20;
  B : constant Mod_Int := 15;
  M : constant Mod_Int := A + B;
  -- No overflow here,
  -- M = (20 + 15) mod 32 = 3
begin
  for I in 1 .. M loop
    Put_Line ("Hello, World!");
  end loop;
end Main;
```

(continues on next page)
Unlike in C/C++, since this wraparound behavior is guaranteed by the Ada specification, you can rely on it to implement portable code. Also, being able to leverage the wrapping on arbitrary bounds is very useful — the modulus does not need to be a power of 2 — to implement certain algorithms and data structures, such as ring buffers\textsuperscript{10}.

### 5.4 Enumerations

Enumeration types are another nicety of Ada's type system. Unlike C's enums, they are not integers, and each new enumeration type is incompatible with other enumeration types. Enumeration types are part of the bigger family of discrete types, which makes them usable in certain situations that we will describe later but one context that we have already seen is a case statement.

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Enumeration_Example is
  type Days is (Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday);
  -- An enumeration type
begin
  for I in Days loop
    case I is
    when Saturday .. Sunday =>
      Put_Line ("Week end!");
    when Monday .. Friday =>
      Put_Line ("Hello on 
& Days'Image (I));
      -- 'Image attribute, works on enums too
    end case;
  end loop;
end Enumeration_Example;
```

**Runtime output**

Hello, World!
Hello, World!
Hello, World!

Introduction to Ada

Hello on MONDAY
Hello on TUESDAY
Hello on WEDNESDAY
Hello on THURSDAY
Hello on FRIDAY
Week end!
Week end!

Enumeration types are powerful enough that, unlike in most languages, they’re used to define the standard Boolean type:

```ada
type Boolean is (False, True);
```

As mentioned previously, every "built-in" type in Ada is defined with facilities generally available to the user.

### 5.5 Floating-point types

#### 5.5.1 Basic properties

Like most languages, Ada supports floating-point types. The most commonly used floating-point type is `Float`:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Floating_Point_Demo is
  A : constant Float := 2.5;
begin
  Put_Line ("The value of A is ", Float'Image (A));
end Floating_Point_Demo;
```

The application will display `2.5` as the value of `A`.

The Ada language does not specify the precision (number of decimal digits in the mantissa) for Float; on a typical 32-bit machine the precision will be 6.

All common operations that could be expected for floating-point types are available, including absolute value and exponentiation. For example:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Floating_Point_Operations is
  A : Float := 2.5;
begin
  -- Listing 7: floating_point_operations.adb
```

(continues on next page)
A := \texttt{abs} (A - 4.5);
Put_Line ("The value of A is " & 	exttt{Float'Image} (A));
A := A ** 2 + 1.0;
Put_Line ("The value of A is " & 	exttt{Float'Image} (A));
end Floating_Point_Operations;

Code block metadata

Project: Courses.Intro_To_Ada.Strongly_Typed.Language.Floating_Point_Operations

MD5: c280e0f23e020aaee1a8777e7fb4c242

Runtime output

The value of A is 2.00000E+00
The value of A is 5.00000E+00

The value of A is 2.0 after the first operation and 5.0 after the second operation.

In addition to \texttt{Float}, an Ada implementation may offer data types with higher precision such as \texttt{Long_Float} and \texttt{Long_Long_Float}. Like \texttt{Float}, the standard does not indicate the exact precision of these types: it only guarantees that the type \texttt{Long_Float}, for example, has at least the precision of \texttt{Float}. In order to guarantee that a certain precision requirement is met, we can define custom floating-point types, as we will see in the next section.

5.5.2 Precision of floating-point types

Ada allows the user to specify the precision for a floating-point type, expressed in terms of decimal digits. Operations on these custom types will then have at least the specified precision. The syntax for a simple floating-point type declaration is:

\texttt{type T is digits \textless number_of_decimal_digits\textgreater ;}

The compiler will choose a floating-point representation that supports the required precision. For example:

\begin{verbatim}
with Ada.Text_IO; use Ada.Text_IO;

procedure Custom_Floating_Types is
  type T3 is digits 3;
  type T15 is digits 15;
  type T18 is digits 18;
begin
  Put_Line ("T3 requires " & Integer'Image (T3'Size) & " bits");
  Put_Line ("T15 requires " & Integer'Image (T15'Size) & " bits");
  Put_Line ("T18 requires " & Integer'Image (T18'Size) & " bits");
end Custom_Floating_Types;
\end{verbatim}

Code block metadata
Introduction to Ada

Runtime output

T3 requires 32 bits
T15 requires 64 bits
T18 requires 128 bits

In this example, the attribute 'Size is used to retrieve the number of bits used for the specified data type. As we can see by running this example, the compiler allocates 32 bits for T3, 64 bits for T15 and 128 bits for T18. This includes both the mantissa and the exponent.

The number of digits specified in the data type is also used in the format when displaying floating-point variables. For example:

Listing 9: display_custom_floating_types.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Display_Custom_Floating_Types is
  type T3 is digits 3;
  type T18 is digits 18;
  C1 : constant := 1.0e-4;
  A : constant T3 := 1.0 + C1;
  B : constant T18 := 1.0 + C1;
begin
  Put_Line ("The value of A is ", T3'Image (A));
  Put_Line ("The value of B is ", T18'Image (B));
end Display_Custom_Floating_Types;
```

Code block metadata

Runtime output

The value of A is 1.00E+00
The value of B is 1.00010000000000000E+00

As expected, the application will display the variables according to specified precision (1.00E+00 and 1.00010000000000000E+00).

5.5.3 Range of floating-point types

In addition to the precision, a range can also be specified for a floating-point type. The syntax is similar to the one used for integer data types — using the range keyword. This simple example creates a new floating-point type based on the type Float, for a normalized range between -1.0 and 1.0:
Listing 10: floating_point_range.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Floating_Point_Range is
  type T_Norm is new Float range -1.0 .. 1.0;
  A : T_Norm;
begin
  A := 1.0;
  Put_Line ("The value of A is ",
             & T_Norm'Image (A));
end Floating_Point_Range;
```

Code block metadata

Project: Courses.Intro_To_Ada.Strongly_Typed_Language.Floating_Point_Range
MD5: b43d596682aa0fa1124a3a3d0596abc

Runtime output

The value of A is 1.00000E+00

The application is responsible for ensuring that variables of this type stay within this range; otherwise an exception is raised. In this example, the exception Constraint_Error is raised when assigning 2.0 to the variable A:

Listing 11: floating_point_range_exception.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Floating_Point_Range_Exception is
  type T_Norm is new Float range -1.0 .. 1.0;
  A : T_Norm;
begin
  A := 2.0;
  Put_Line ("The value of A is ",
             & T_Norm'Image (A));
end Floating_Point_Range_Exception;
```

Code block metadata

Project: Courses.Intro_To_Ada.Strongly_Typed_Language.Floating_Point_Range_Exception
MD5: ecda66589ba28e453956dca159ea5f0d

Build output

floating_point_range_exception.adb:7:09: warning: value not in range of type "T_Norm" defined at line 4 [enabled by default]
floating_point_range_exception.adb:7:09: warning: Constraint_Error will be raised at run time [enabled by default]

Runtime output

raised CONSTRAINT_ERROR : floating_point_range_exception.adb:7 range check failed

Ranges can also be specified for custom floating-point types. For example:
Introduction to Ada

Listing 12: custom_range_types.adb

with Ada.Text_IO; use Ada.Text_IO;
with Ada.Numerics; use Ada.Numerics;

procedure Custom_Range_Types is
  type T6_Inv_Trig is digits 6 range -Pi / 2.0 .. Pi / 2.0;
begin
  null;
end Custom_Range_Types;

5.6 Strong typing

As noted earlier, Ada is strongly typed. As a result, different types of the same family are incompatible with each other; a value of one type cannot be assigned to a variable from the other type. For example:

Listing 13: illegal_example.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Illegal_Example is
  -- Declare two different floating point types
  type Meters is new Float;
  type Miles is new Float;
  Dist_Imperial : Miles;
  Dist_Metric : constant Meters := 1000.0;
begin
  -- Not correct: types mismatch
  Dist_Imperial := Dist_Metric * 621.371e-6;
  Put_Line (Miles'Image (Dist_Imperial));
end Illegal_Example;

A consequence of these rules is that, in the general case, a "mixed mode" expression like 2 * 3.0 will trigger a compilation error. In a language like C or Python, such expressions are made valid by implicit conversions. In Ada, such conversions must be made explicit:
Listing 14: conv.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Conv is
    type Meters is new Float;
    type Miles is new Float;
    Dist_Imperial : Miles;
    Dist_Metric : constant Meters := 1000.0;

begin
    Dist_Imperial := Miles (Dist_Metric) * 621.371e-6;
    -- Type conversion, from Meters to Miles
    -- Now the code is correct
    Put_Line (Miles'Image (Dist_Imperial));
end Conv;
```

Code block metadata

Project: Courses.Intro_To_Ada.Strongly_Typed_Language.Imperial_Metric
MD5: e455641e86227e80e5f920b5af6315d4

Runtime output

```
6.21371E-01
```

Of course, we probably do not want to write the conversion code every time we convert from meters to miles. The idiomatic Ada way in that case would be to introduce conversion functions along with the types.

Listing 15: conv.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Conv is
    type Meters is new Float;
    type Miles is new Float;

    -- Function declaration, like procedure
    -- but returns a value.
    function To_Miles (M : Meters) return Miles is
        ^ Return type
    begin
        return Miles (M) * 621.371e-6;
    end To_Miles;

    Dist_Imperial : Miles;
    Dist_Metric : constant Meters := 1000.0;

begin
    Dist_Imperial := To_Miles (Dist_Metric);
    Put_Line (Miles'Image (Dist_Imperial));
end Conv;
```

Runtime output

```
5.6
```

5.6. Strong typing
If you write a lot of numeric code, having to explicitly provide such conversions might seem painful at first. However, this approach brings some advantages. Notably, you can rely on the absence of implicit conversions, which will in turn prevent some subtle errors.

In other languages

In C, for example, the rules for implicit conversions may not always be completely obvious. In Ada, however, the code will always do exactly what it seems to do. For example:

```c
int a = 3, b = 2;
float f = a / b;
```

This code will compile fine, but the result of \( f \) will be 1.0 instead of 1.5, because the compiler will generate an integer division (three divided by two) that results in one. The software developer must be aware of data conversion issues and use an appropriate casting:

```c
int a = 3, b = 2;
float f = (float)a / b;
```

In the corrected example, the compiler will convert both variables to their corresponding floating-point representation before performing the division. This will produce the expected result.

This example is very simple, and experienced C developers will probably notice and correct it before it creates bigger problems. However, in more complex applications where the type declaration is not always visible — e.g. when referring to elements of a `struct` — this situation might not always be evident and quickly lead to software defects that can be harder to find.

The Ada compiler, in contrast, will always reject code that mixes floating-point and integer variables without explicit conversion. The following Ada code, based on the erroneous example in C, will not compile:

```ada
procedure Main is
  A : Integer := 3;
  B : Integer := 2;
  F : Float;
begin
  F := A / B;
end Main;
```

```xml
Code block metadata
Project: Courses.Intro_To_Ada.Strongly_Typed_Language.Implicit_Cast
MD5: 38a8fcca6608c2b22e22940052ab8dd62f4
Build output
main.adb:6:11: error: found type "Standard.Integer"
gprbuild: *** compilation phase failed
```

The offending line must be changed to \( F := \text{Float}(A) / \text{Float}(B); \) in order to be accepted by the compiler.
You can use Ada's strong typing to help enforce invariants in your code, as in the example above: Since Miles and Meters are two different types, you cannot mistakenly convert an instance of one to an instance of the other.

## 5.7 Derived types

In Ada you can create new types based on existing ones. This is very useful: you get a type that has the same properties as some existing type but is treated as a distinct type in the interest of strong typing.

Listing 17: main.adb

```ada
procedure Main is
  -- ID card number type,
  -- incompatible with Integer.
  type Social_Security_Number is new Integer
    range 0 .. 999_99_9999;
  -- ^ Since a SSN has 9 digits
  -- max., and cannot be
  -- negative, we enforce
  -- a validity constraint.

  SSN : Social_Security_Number :=
    555_55_5555;
  -- ^ You can put underscores as
  -- formatting in any number.

  I : Integer;

  -- The value -1 below will cause a
  -- runtime error and a compile time
  -- warning with GNAT.
  Invalid : Social_Security_Number := -1;
begin
  -- Illegal, they have different types:
  I := SSN;
  -- Likewise illegal:
  SSN := I;
  -- OK with explicit conversion:
  I := Integer (SSN);
  -- Likewise OK:
  SSN := Social_Security_Number (I);
end Main;
```

Build output

main.adb:21:40: warning: value not in range of type "Social_Security_Number" defined at line 4 [enabled by default]
main.adb:21:40: warning: Constraint_Error will be raised at run time [enabled by default]

(continues on next page)
main.adb:24:09: error: expected type "Standard.Integer"
main.adb:24:09: error: found type "Social_Security_Number" defined at line 4
main.adb:27:11: error: expected type "Social_Security_Number" defined at line 4
main.adb:27:11: error: found type "Standard.Integer"
gprbuild: *** compilation phase failed

The type Social_Security is said to be a **derived type**; its **parent type** is **Integer**.

As illustrated in this example, you can refine the valid range when defining a derived scalar type (such as integer, floating-point and enumeration).

The syntax for enumerations uses the **range <range>** syntax:

### Listing 18: greet.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  type Days is (Monday, Tuesday, Wednesday,
               Thursday, Friday,
               Saturday, Sunday);

  type Weekend_Days is new
    Days range Saturday .. Sunday;
    -- New type, where only Saturday and Sunday
    -- are valid literals.

begin
  null;
end Greet;
```

### 5.8 Subtypes

As we are starting to see, types may be used in Ada to enforce constraints on the valid range of values. However, we sometimes want to enforce constraints on some values while staying within a single type. This is where subtypes come into play. A subtype does not introduce a new type.

### Listing 19: greet.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  type Days is (Monday, Tuesday, Wednesday,
               Thursday, Friday,
               Saturday, Sunday);

  subtype Weekend_Days is
    Days range Saturday .. Sunday;
    -- ^ Constraint of the subtype

  M : Days := Sunday;
```

(continues on next page)
S : Weekend_Days := M;
-- No error here, Days and Weekend_Days
-- are of the same type.
begin
  for I in Days loop
    case I is
      -- Just like a type, a subtype can
      -- be used as a range
      when Weekend_Days =>
        Put_Line ("Week end!");
      when others =>
        Put_Line ("Hello on "
                  & Days'Image (I));
    end case;
  end loop;
end Greet;

Code block metadata

Project: Courses.Intro_To_Ada.Strongly_Typed_Language.Days_Subtype

### 5.8.1 Subtypes as type aliases

Previously, we've seen that we can create new types by declaring e.g. `type Miles is new Float`. We could also create type aliases, which generate alternative names — aliases — for known types. Note that type aliases are sometimes called type synonyms.

We achieve this in Ada by using subtypes without new constraints. In this case, however, we don't get all of the benefits of Ada's strong type checking. Let's rewrite an example using type aliases:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Undetected_Imperial_Metric_Error is
  -- Declare two type aliases
  subtype Meters is Float;
  subtype Miles is Float;
  Dist_Imperial : Miles;

  -- Declare a constant
  Dist_Metric : constant Meters := 100.0;

begin
  -- No conversion to Miles type required:
  Dist_Imperial := (Dist_Metric * 1609.0) / 1000.0;

  -- Not correct, but undetected:
  Dist_Imperial := Dist_Metric;

  Put_Line (Miles'Image (Dist_Imperial));
end Undetected_Imperial_Metric_Error;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Strongly_Typed_Language.Undetected_Imperial_Metric_Error

MD5: cdb8f949c69f3c480502b859dac298ee
Runtime output

1.00000E+02

In the example above, the fact that both Meters and Miles are subtypes of Float allows us to mix variables of both types without type conversion. This, however, can lead to all sorts of programming mistakes that we'd like to avoid, as we can see in the undetected error highlighted in the code above. In that example, the error in the assignment of a value in meters to a variable meant to store values in miles remains undetected because both Meters and Miles are subtypes of Float. Therefore, the recommendation is to use strong typing — via type X is new Y — for cases such as the one above.

There are, however, many situations where type aliases are useful. For example, in an application that uses floating-point types in multiple contexts, we could use type aliases to indicate additional meaning to the types or to avoid long variable names. For example, instead of writing:

```plaintext
Paid_Amount, Due_Amount : Float;
```

We could write:

```plaintext
subtype Amount is Float;
Paid, Due : Amount;
```

In other languages

In C, for example, we can use a typedef declaration to create a type alias. For example:

```plaintext
typedef float meters;
```

This corresponds to the declaration that we've seen above using subtypes. Other programming languages include this concept in similar ways. For example:

- C++: using meters = float;
- Swift: typealias Meters = Double
- Kotlin: typealias Meters = Double
- Haskell: type Meters = Float

Note, however, that subtypes in Ada correspond to type aliases if, and only if, they don't have new constraints. Thus, if we add a new constraint to a subtype declaration, we don't have a type alias anymore. For example, the following declaration can't be considered a type alias of Float:

```plaintext
subtype Meters is Float range 0.0 .. 1_000_000.0;
```

Let's look at another example:

```plaintext
subtype Degree_Celsius is Float;

subtype Liquid_Water_Temperature is
    Degree_Celsius range 0.0 .. 100.0;

subtype Running_Water_Temperature is
    Liquid_Water_Temperature;
```

In this example, Liquid_Water_Temperature isn't an alias of Degree_Celsius, since it adds a new constraint that wasn't part of the declaration of the Degree_Celsius. However, we do have two type aliases here:
• Degree_Celsius is an alias of Float;
• Running_Water_Temperature is an alias of Liquid_Water_Temperature, even if Liquid_Water_Temperature itself has a constrained range.
So far, all the types we have encountered have values that are not decomposable: each instance represents a single piece of data. Now we are going to see our first class of composite types: records.

Records allow composing a value out of instances of other types. Each of those instances will be given a name. The pair consisting of a name and an instance of a specific type is called a field, or a component.

### 6.1 Record type declaration

Here is an example of a simple record declaration:

```haskell
type Date is record
  -- The following declarations are components of the record
  Day : Integer range 1 .. 31;
  Month : Months;
  -- You can add custom constraints on fields
  Year : Integer range 1 .. 3000;
end record;
```

Fields look a lot like variable declarations, except that they are inside of a record definition. And as with variable declarations, you can specify additional constraints when supplying the subtype of the field.

```haskell
type Date is record
  Day : Integer range 1 .. 31;
  Month : Months := January;
  -- This component has a default value
  Year : Integer range 1 .. 3000 := 2012;
  -- ^^^^ Default value
end record;
```

Record components can have default values. When a variable having the record type is declared, a field with a default initialization will be automatically set to this value. The value can be any expression of the component type, and may be run-time computable.

In the remaining sections of this chapter, we see how to use record types. In addition to that, we discuss more about records in another chapter (page 97).
6.2 Aggregates

Records have a convenient notation for expressing values, illustrated above. This notation is called aggregate notation, and the literals are called aggregates. They can be used in a variety of contexts that we will see throughout the course, one of which is to initialize records.

An aggregate is a list of values separated by commas and enclosed in parentheses. It is allowed in any context where a value of the record is expected.

Values for the components can be specified positionally, as in Ada_Birthday example, or by name, as in Leap_Day_2020. A mixture of positional and named values is permitted, but you cannot use a positional notation after a named one.

6.3 Component selection

To access components of a record instance, you use an operation that is called component selection. This is achieved by using the dot notation. For example, if we declare a variable Some_Day of the Date record type mentioned above, we can access the Year component by writing Some_Day.Year.

Let’s look at an example:

Listing 1: record_selection.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Record_Selection is

  type Months is
    (January, February, March, April,
     May, June, July, August, September,
     October, November, December);

  type Date is record
    Day : Integer range 1 .. 31;
    Month : Months;
    Year : Integer range 1 .. 3000 := 2032;
  end record;

  procedure Display_Date (D : Date) is
  begin
    Put_Line ("Day:" & Integer'Image (D.Day) & ", Month: " 
              & Months'Image (D.Month) & ", Year:" 
              & Integer'Image (D.Year));
  end Display_Date;

  Some_Day : Date := (1, January, 2000);
```

(continues on next page)
begin
    Display_Date (Some_Day);
    Put_Line ("Changing year...");
    Some_Day.Year := 2001;
    Display_Date (Some_Day);
end Record_Selection;

As you can see in this example, we can use the dot notation in the expression D.Year or Some_Day.Year to access the information stored in that component, as well as to modify this information in assignments. To be more specific, when we use D.Year in the call to Put_Line, we're retrieving the information stored in that component. When we write Some_Day.Year := 2001, we're overwriting the information that was previously stored in the Year component of Some_Day.

6.4 Renaming

In previous chapters, we've discussed subprogram (page 28) and package (page 42) renaming. We can rename record components as well. Instead of writing the full component selection using the dot notation, we can declare an alias that allows us to access the same component. This is useful to simplify the implementation of a subprogram, for example.

We can rename record components by using the renames keyword in a variable declaration. For example:

Some_Day : Date;
Y : Integer renames Some_Day.Year;

Here, Y is an alias, so that every time we using Y, we are really using the Year component of Some_Day.

Let's look at a complete example:

Listing 2: dates.ads

package Dates is

    type Months is
        (January, February, March, April,
         May, June, July, August, September,
         October, November, December);

    type Date is record
        Day : Integer range 1 .. 31;
        Month : Months;
end Dates;
Introduction to Ada

Year : Integer range 1 .. 3000 := 2032;

procedure Increase_Month
(Some_Day : in out Date);

procedure Display_Month
(Some_Day : Date);

end Dates;

Listing 3: dates.adb

with Ada.Text_IO; use Ada.Text_IO;

package body Dates is

procedure Increase_Month
(Some_Day : in out Date)
is
  -- Renaming components from
  -- the Date record
  M : Months renames Some_Day.Month;
  Y : Integer renames Some_Day.Year;
  -- Renaming function (for Months
  -- enumeration)
  function Next (M : Months)
    return Months
    renames Months' Succ;
begin
  if M = December then
    M := January;
    Y := Y + 1;
  else
    M := Next (M);
  end if;
end Increase_Month;

procedure Display_Month
(Some_Day : Date)
is
  -- Renaming components from
  -- the Date record
  M : Months renames Some_Day.Month;
  Y : Integer renames Some_Day.Year;
begin
  Put_Line ("Month: "
            & Months' Image (M)
            & ", Year:"
            & Integer' Image (Y));
end Display_Month;

end Dates;

Listing 4: main.adb

with Ada.Text_IO; use Ada.Text_IO;
with Dates;  use Dates;

(continues on next page)
procedure Main is
  D : Date := (1, January, 2000);
begin
  Display_Month (D);
  Put_Line ("Increasing month...");
  Increase_Month (D);
  Display_Month (D);
end Main;

Code block metadata
Project: Courses.Intro_To_Ada.Arrays.Record_Component_Renaming
MD5: 905390bd02b8417039052218800975a3

Runtime output
Month: JANUARY, Year: 2000
Increasing month...
Month: FEBRUARY, Year: 2000

We apply renaming to two components of the Date record in the implementation of the Increase_Month procedure. Then, instead of directly using Some_Day.Month and Some_Day.Year in the next operations, we simply use the renamed versions M and Y.

Note that, in the example above, we also rename Months.'Succ — which is the function that gives us the next month — to Next.
Arrays provide another fundamental family of composite types in Ada.

## 7.1 Array type declaration

Arrays in Ada are used to define contiguous collections of elements that can be selected by indexing. Here's a simple example:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  type My_Int is range 0 .. 1000;
  type Index is range 1 .. 5;

  type My_Int_Array is
    array (Index) of My_Int;
  -- ^ Type of elements
  -- ^ Bounds of the array
  Arr : My_Int_Array := (2, 3, 5, 7, 11);
  -- ^ Array literal
  -- (aggregate)

  V : My_Int;

begin
  for I in Index loop
    V := Arr (I);  -- ^ Take the Ith element
    Put (My_Int'Image (V));
  end loop;
  New_Line;
end Greet;
```

### Code block metadata

- **Project:** Courses.Intro_To_Ada.Arrays.Greet
- **MD5:** ffdd2ba2322b0946dfcac3a55bce5270

### Runtime output

```
2 3 5 7 11
```

The first point to note is that we specify the index type for the array, rather than its size. Here we declared an integer type named `Index` ranging from 1 to 5, so each array instance will have 5 elements, with the initial element at index 1 and the last element at index 5.
Although this example used an integer type for the index, Ada is more general: any discrete type is permitted to index an array, including *Enum types* (page 47). We will soon see what that means.

Another point to note is that querying an element of the array at a given index uses the same syntax as for function calls: that is, the array object followed by the index in parentheses. Thus when you see an expression such as `A (B)`, whether it is a function call or an array subscript depends on what `A` refers to.

Finally, notice how we initialize the array with the `(2, 3, 5, 7, 11)` expression. This is another kind of aggregate in Ada, and is in a sense a literal expression for an array, in the same way that `3` is a literal expression for an integer. The notation is very powerful, with a number of properties that we will introduce later. A detailed overview appears in the notation of *aggregate types* (page 85).

Unrelated to arrays, the example also illustrated two procedures from *Ada.Text_IO*:

- Put, which displays a string without a terminating end of line
- New_Line, which outputs an end of line

Let's now delve into what it means to be able to use any discrete type to index into the array.

**In other languages**

Semantically, an array object in Ada is the entire data structure, and not simply a handle or pointer. Unlike C and C++, there is no implicit equivalence between an array and a pointer to its initial element.
One effect is that the bounds of an array can be any values. In the first example we con-
structed an array type whose first index is 1, but in the example above we declare an array
type whose first index is 11.

That's perfectly fine in Ada, and moreover since we use the index type as a range to iterate
over the array indices, the code using the array does not need to change.

That leads us to an important consequence with regard to code dealing with arrays. Since
the bounds can vary, you should not assume / hard-code specific bounds when iterating /
using arrays. That means the code above is good, because it uses the index type, but a for
loop as shown below is bad practice even though it works correctly:

```ada
for I in 11 .. 15 loop
  Tab (I) := Tab (I) + 2;
end loop;
```

Since you can use any discrete type to index an array, enumeration types are permitted.

Listing 3: month_example.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Month_Example is
  type Month_Duration is range 1 .. 31;
  type Month is (Jan, Feb, Mar, Apr,
                May, Jun, Jul, Aug,
                Sep, Oct, Nov, Dec);

  type My_Int_Array is
    array (Month) of Month_Duration;
  -- ^ Can use an enumeration type
  -- as the index

  Tab : constant My_Int_Array :=
    (31, 28, 31, 30, 31, 30, 31, 31, 29, 31, 30, 31, 30, 31, 31, 29, 31);
  -- Maps months to number of days
  -- (ignoring leap years)

  Feb_Days : Month_Duration := Tab (Feb);
  -- Number of days in February

begin
  for M in Month loop
    Put_Line
      (Month'Image (M) & " has "
       & Month_Duration'Image (Tab (M))
       & " days.");
  -- ^ Concatenation operator
end loop;
end Month_Example;
```

Code block metadata

Project: Courses.Intro_To_Ada.Arrays.Month_Example
MD5: 420bb8faa36d0e6fd3d071c76c2033d21

Runtime output

JAN has 31 days.
FEB has 28 days.
MAR has 31 days.

(continues on next page)

7.1. Array type declaration
APR has 30 days.
MAY has 31 days.
JUN has 30 days.
JUL has 31 days.
AUG has 31 days.
SEP has 30 days.
OCT has 31 days.
NOV has 30 days.
DEC has 31 days.

In the example above, we are:

- Creating an array type mapping months to month durations in days.
- Creating an array, and instantiating it with an aggregate mapping months to their actual durations in days.
- Iterating over the array, printing out the months, and the number of days for each.

Being able to use enumeration values as indices is very helpful in creating mappings such as shown above one, and is an often used feature in Ada.

7.2 Indexing

We have already seen the syntax for selecting elements of an array. There are however a few more points to note.

First, as is true in general in Ada, the indexing operation is strongly typed. If you use a value of the wrong type to index the array, you will get a compile-time error.

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  type My_Int is range 0 .. 1000;
  type My_Index is range 1 .. 5;
  type Your_Index is range 1 .. 5;
  type My_Int_Array is array (My_Index) of My_Int;
  Tab : My_Int_Array := (2, 3, 5, 7, 11);
begin
  for I in Your_Index loop
    Put (My_Int'Image (Tab (I)));
    -- ^ Compile time error
  end loop;
end Greet;
```

Code block metadata

Project: Courses.Intro_To_Ada.Arrays.Greet_2
MD5: 54543017e4ec69d24bf9e43d507b50e6
Second, arrays in Ada are bounds checked. This means that if you try to access an element outside of the bounds of the array, you will get a run-time error instead of accessing random memory as in unsafe languages.

Listing 5: greet.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  type My_Int is range 0 .. 1000;
  type Index is range 1 .. 5;
  type My_Int_Array is array (Index) of My_Int;
  Tab : My_Int_Array := (2, 3, 5, 7, 11);
begin
  for I in Index range 2 .. 6 loop
    Put (My_Int'Image (Tab (I)));
    -- ^ Will raise an exception when I = 6
  end loop;
  New_Line;
end Greet;
```

Runtime output

raised CONSTRAINT_ERROR : greet.adb:12 range check failed
7.3 Simpler array declarations

In the previous examples, we have always explicitly created an index type for the array. While this can be useful for typing and readability purposes, sometimes you simply want to express a range of values. Ada allows you to do that, too.

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Simple_Array_Bounds is
  type My_Int is range 0 .. 1000;

  type My_Int_Array is array (1 .. 5) of My_Int;
  -- ^ Subtype of Integer

  Tab : constant My_Int_Array :=
    (2, 3, 5, 7, 11);

begin
  for I in 1 .. 5 loop
    -- ^ Subtype of Integer
    Put (My_Int'Image (Tab (I)));
  end loop;

end Simple_Array_Bounds;
```

This example defines the range of the array via the range syntax, which specifies an anonymous subtype of Integer and uses it to index the array.

This means that the type of the index is `Integer`. Similarly, when you use an anonymous range in a for loop as in the example above, the type of the iteration variable is also `Integer`, so you can use `I` to index `Tab`.

You can also use a named subtype for the bounds for an array.

7.4 Range attribute

We noted earlier that hard coding bounds when iterating over an array is a bad idea, and showed how to use the array’s index type/subtype to iterate over its range in a `for` loop. That raises the question of how to write an iteration when the array has an anonymous range for its bounds, since there is no name to refer to the range. Ada solves that via several attributes of array objects:

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Range_Example is
  -- (continues on next page)
```

This example defines the range of the array via the range syntax, which specifies an anonymous subtype of Integer and uses it to index the array.

This means that the type of the index is `Integer`. Similarly, when you use an anonymous range in a for loop as in the example above, the type of the iteration variable is also `Integer`, so you can use `I` to index `Tab`.

You can also use a named subtype for the bounds for an array.
4 type My_Int is range 0 .. 1000;
5 type My_Int_Array is
6 array (1 .. 5) of My_Int;
7 Tab : constant My_Int_Array :=
8 (2, 3, 5, 7, 11);
9 begin
10 for I in Tab'Range loop
11 -- ^ Gets the range of Tab
12 Put (My_Int'Image (Tab (I)));
13 end loop;
14 New_Line;
15 end Range_Example;
16
Code block metadata

Runtime output

2 3 5 7 11

If you want more fine grained control, you can use the separate attributes 'First and 'Last.

Listing 8: array_attributes_example.adb

1 with Ada.Text_IO; use Ada.Text_IO;
2
3 procedure Array_Attributes_Example is
4 type My_Int is range 0 .. 1000;
5 type My_Int_Array is
6 array (1 .. 5) of My_Int;
7 Tab : My_Int_Array :=
8 (2, 3, 5, 7, 11);
9 begin
10 for I in Tab'First .. Tab'Last - 1 loop
11 -- ^ Iterate on every index
12 -- except the last
13 Put (My_Int'Image (Tab (I)));
14 end loop;
15 New_Line;
16 end Array_Attributes_Example;
17

Runtime output

2 3 5 7

The 'Range, 'First and 'Last attributes in these examples could also have been applied to the array type name, and not just the array instances.

Although not illustrated in the above examples, another useful attribute for an array instance A is A'Length, which is the number of elements that A contains.
It is legal and sometimes useful to have a "null array", which contains no elements. To get this effect, define an index range whose upper bound is less than the lower bound.

### 7.5 Unconstrained arrays

Let's now consider one of the most powerful aspects of Ada's array facility.

Every array type we have defined so far has a fixed size: every instance of this type will have the same bounds and therefore the same number of elements and the same size.

However, Ada also allows you to declare array types whose bounds are not fixed: in that case, the bounds will need to be provided when creating instances of the type.

Listing 9: unconstrained_array_example.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Unconstrained_Array_Example is

  type Days is (Monday, Tuesday, Wednesday,
                Thursday, Friday,
                Saturday, Sunday);

  type Workload_Type is array (Days range <>) of Natural;
  -- Indefinite array type
  -- ^ Bounds are of type Days,
  -- but not known

  Workload : constant Workload_Type (Monday .. Friday) :=
  -- ^ Specify the bounds
  -- when declaring
  -- (Friday => 7, others => 8);
  -- ^ Default value
  -- ^ Specify element by name of index

  begin
    for I in Workload'Range loop
      Put_Line (Integer'Image (Workload (I)));
    end loop;
  end Unconstrained_Array_Example;
```

The fact that the bounds of the array are not known is indicated by the Days range <> syntax. Given a discrete type Discrete_Type, if we use Discrete_Type for the index in an array type then Discrete_Type serves as the type of the index and comprises the range of index values for each array instance.

If we define the index as Discrete_Type range <> then Discrete_Type serves as the type of the index, but different array instances may have different bounds from this type.
An array type that is defined with the Discrete_Type range <> syntax for its index is referred to as an unconstrained array type, and, as illustrated above, the bounds need to be provided when an instance is created.

The above example also shows other forms of the aggregate syntax. You can specify associations by name, by giving the value of the index on the left side of an arrow association. 1 => 2 thus means "assign value 2 to the element at index 1 in my array". others => 8 means "assign value 8 to every element that wasn't previously assigned in this aggregate".

Attention: The so-called "box" notation (<>) is commonly used as a wildcard or placeholder in Ada. You will often see it when the meaning is "what is expected here can be anything".

In other languages

While unconstrained arrays in Ada might seem similar to variable length arrays in C, they are in reality much more powerful, because they're truly first-class values in the language. You can pass them as parameters to subprograms or return them from functions, and they implicitly contain their bounds as part of their value. This means that it is useless to pass the bounds or length of an array explicitly along with the array, because they are accessible via the 'First, 'Last, 'Range and 'Length attributes explained earlier.

Although different instances of the same unconstrained array type can have different bounds, a specific instance has the same bounds throughout its lifetime. This allows Ada to implement unconstrained arrays efficiently; instances can be stored on the stack and do not require heap allocation as in languages like Java.

7.6 Predefined array type: String

A recurring theme in our introduction to Ada types has been the way important built-in types like Boolean or Integer are defined through the same facilities that are available to the user. This is also true for strings: The String type in Ada is a simple array.

Here is how the string type is defined in Ada:

type String is
  array (Positive range <>) of Character;

The only built-in feature Ada adds to make strings more ergonomic is custom literals, as we can see in the example below.

Hint: String literals are a syntactic sugar for aggregates, so that in the following example, A and B have the same value.

Listing 10: string_literals.ads

```ada
package String_Literals is
  -- Those two declarations are equivalent
  A : String (1 .. 11) := "Hello World";
  B : String (1 .. 11) := ('H', 'e', 'l', 'l', 'o', ' ',
                     'W', 'o', 'r', 'l', 'd');
end String_Literals;
```

Code block metadata
Introduction to Ada

Project: Courses.Intro_To_Ada.Arrays.String_Literals
MD5: 8e5871c8ead4ff8da643539857e23b30

Listing 11: greet.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  Message : String (1 .. 11) := "dlroW olleH";
  -- ^ Pre-defined array type.
  -- Component type is Character
begin
  for I in reverse Message'Range loop
    -- ^ Iterate in reverse order
    Put (Message (I));
  end loop;
  New_Line;
end Greet;

However, specifying the bounds of the object explicitly is a bit of a hassle; you have to manually count the number of characters in the literal. Fortunately, Ada gives you an easier way.

You can omit the bounds when creating an instance of an unconstrained array type if you supply an initialization, since the bounds can be deduced from the initialization expression.

Listing 12: greet.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Greet is
  Message : constant String := "dlroW olleH";
  -- ^ Bounds are automatically computed from initialization value
begin
  for I in reverse Message'Range loop
    Put (Message (I));
  end loop;
  New_Line;
end Greet;

Code block metadata

Project: Courses.Intro_To_Ada.Arrays.Greet_5
MD5: 21448a1007a07ec9d434880628625c3f

Runtime output

Hello World

Listing 13: main.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
  type Integer_Array is
    array (Natural range <>) of Integer;
  My_Array : constant Integer_Array :=
8 (1, 2, 3, 4);
9 -- ^^^^^^^^^^^^^^^^^^^^^
10 -- Bounds are automatically
11 -- computed from
12 -- initialization value
begin
  null;
end Main;

Attention: As you can see above, the standard String type in Ada is an array. As such, it shares the advantages and drawbacks of arrays: a String value is stack allocated, it is accessed efficiently, and its bounds are immutable.

If you want something akin to C++'s std::string, you can use Unbounded Strings (page 242) from Ada's standard library. This type is more like a mutable, automatically managed string buffer to which you can add content.

7.7 Restrictions

A very important point about arrays: bounds have to be known when instances are created. It is for example illegal to do the following.

```
declare
  A : String;
begin
  A := "World";
end;
```

Also, while you of course can change the values of elements in an array, you cannot change the array's bounds (and therefore its size) after it has been initialized. So this is also illegal:

```
declare
  A : String := "Hello";
begin
  A := "World";  -- OK: Same size
  A := "Hello World";  -- Not OK: Different size
end;
```

Also, while you can expect a warning for this kind of error in very simple cases like this one, it is impossible for a compiler to know in the general case if you are assigning a value of the correct length, so this violation will generally result in a run-time error.

Attention

While we will learn more about this later, it is important to know that arrays are not the only types whose instances might be of unknown size at compile-time.

Such objects are said to be of an indefinite subtype, which means that the subtype size is not known at compile time, but is dynamically computed (at run time).

```
with Ada.Text_IO; use Ada.Text_IO;
procedure Indefinite_Subtypes is
```

(continues on next page)
function Get_Number return Integer is
begin
  return Integer'Value (Get_Line);
end Get_Number;

A : String := "Hello";
-- Indefinite subtype

B : String (1 .. 5) := "Hello";
-- Definite subtype

C : String (1 .. Get_Number);
-- Indefinite subtype
-- (Get Number's value is computed at
-- run-time)
begin
  null;
end Indefinite_Subtypes;

7.8 Returning unconstrained arrays

The return type of a function can be any type; a function can return a value whose size is
unknown at compile time. Likewise, the parameters can be of any type.

For example, this is a function that returns an unconstrained String:

with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
  type Days is (Monday, Tuesday, Wednesday,
               Thursday, Friday,
               Saturday, Sunday);
  function Get_Day_Name (Day : Days := Monday)
    return String is
    begin
      return (case Day is
                when Monday => "Monday",
                when Tuesday => "Tuesday",
                when Wednesday => "Wednesday",
                when Thursday => "Thursday",
                when Friday => "Friday",
                when Saturday => "Saturday",
                when Sunday => "Sunday");
    end Get_Day_Name;

Here, the 'Value attribute converts the string to an integer.
begin
  Put_Line ("First day is ",
            & Get_Day_Name (Days'First));
end Main;

Code block metadata
Project: Courses.Intro.To.Ada.Arrays.Day_Name_1
MD5: 0b7c567c723ded52d8e95c4ef46bcecc

Runtime output
First day is Monday

(This example is for illustrative purposes only. There is a built-in mechanism, the 'Image attribute for scalar types, that returns the name (as a String) of any element of an enumeration type. For example Days'Image(Monday) is "MONDAY".)

In other languages
Returning variable size objects in languages lacking a garbage collector is a bit complicated implementation-wise, which is why C and C++ don't allow it, preferring to depend on explicit dynamic allocation / free from the user.

The problem is that explicit storage management is unsafe as soon as you want to collect unused memory. Ada's ability to return variable size objects will remove one use case for dynamic allocation, and hence, remove one potential source of bugs from your programs.

Rust follows the C/C++ model, but with safe pointer semantics. However, dynamic allocation is still used. Ada can benefit from a possible performance edge because it can use any model.

7.9 Declaring arrays (2)

While we can have array types whose size and bounds are determined at run time, the array's component type needs to be of a definite and constrained type.

Thus, if you need to declare, for example, an array of strings, the String subtype used as component will need to have a fixed size.

Listing 16: show_days.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Days is
  type Days is (Monday, Tuesday, Wednesday,
                Thursday, Friday,
                Saturday, Sunday);

  subtype Day_Name is String (1 .. 2);
  -- Subtype of string with known size

  type Days_Name_Type is
    array (Days) of Day_Name;
  -- ^ Type of the index
  -- ^ Type of the element. 
  -- Must be definite
```

(continues on next page)
Names : constant Days_Name_Type :=
("Mo", "Tu", "We", "Th", "Fr", "Sa", "Su");
-- Initial value given by aggregate
begin
  for I in Names'Range loop
    Put_Line (Names (I));
  end loop;
end Show_Days;

7.10 Array slices

One last feature of Ada arrays that we're going to cover is array slices. It is possible to take
and use a slice of an array (a contiguous sequence of elements) as a name or a value.

Listing 17: main.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Main is
  Buf : String := "Hello ...";
  Full_Name : String := "John Smith";
begin
  Buf (7 .. 9) := "Bob";
  -- Careful! This works because the string
  -- on the right side is the same length as
  -- the replaced slice!
  -- Prints "Hello Bob"
  Put_Line (Buf);
  -- Prints "Hi John"
  Put_Line ("Hi " & Full_Name (1 .. 4));
end Main;
Hello Bob
Hi John

As we can see above, you can use a slice on the left side of an assignment, to replace only part of an array.

A slice of an array is of the same type as the array, but has a different subtype, constrained by the bounds of the slice.

**Attention:** Ada has multidimensional arrays\(^\text{11}\), which are not covered in this course. Slices will only work on one dimensional arrays.

### 7.11 Renaming

So far, we’ve seen that the following elements can be renamed: subprograms (page 28), packages (page 42), and record components (page 63). We can also rename objects by using the renames keyword. This allows for creating alternative names for these objects. Let’s look at an example:

**Listing 18: measurements.ads**

```ada
package Measurements is
    subtype Degree_Celsius is Float;
    Current_Temperature : Degree_Celsius;
end Measurements;
```

**Listing 19: main.adb**

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Measurements;

procedure Main is
    subtype Degrees is
        Measurements.Degree_Celsius;

    T : Degrees
    renames Measurements.Current_Temperature;

begin
    T := 5.0;
    Put_Line (Degrees'Image (T));
    Put_Line (Degrees'Image (Measurements.Current_Temperature));
    T := T + 2.5;
    Put_Line (Degrees'Image (T));
    Put_Line (Degrees'Image (Measurements.Current_Temperature));
end Main;
```

---

In the example above, we declare a variable T by renaming the Current_Temperature object from the Measurements package. As you can see by running this example, both Current_Temperature and its alternative name T have the same values:

- first, they show the value 5.0
- after the addition, they show the value 7.5.

This is because they are essentially referring to the same object, but with two different names.

Note that, in the example above, we're using Degrees as an alias of Degree_Celsius. We discussed this method earlier in the course (page 58).

Renaming can be useful for improving the readability of more complicated array indexing. Instead of explicitly using indices every time we're accessing certain positions of the array, we can create shorter names for these positions by renaming them. Let's look at the following example:

Listing 20: colors.ads

```ada
package Colors is
  type Color is (Black,
                 Red,
                 Green,
                 Blue,
                 White);

  type Color_Array is
    array (Positive range <>) of Color;

  procedure Reverse_It (X : in out Color_Array);
end Colors;
```

Listing 21: colors.adb

```ada
package body Colors is
  procedure Reverse_It (X : in out Color_Array)
  is
    begin
      for I in X'First .. (X'Last + X'First) / 2
        loop
          declare
            Tmp : Color;
            X_Left : Color
              renames X (I);
            X_Right : Color
              renames X (X'Last + X'First - I);
          begin
```

(continues on next page)
In the example above, package Colors implements the procedure Reverse_It by declaring new names for two positions of the array. The actual implementation becomes easy to read:

```
package Colors is

    procedure Reverse_It (Colors : in out Color_Array;
                            Tmp, X_Left, X_Right : out Integer);

end Colors;
```

```ada
package Colors is

    procedure Reverse_It (Colors : in out Color_Array;
                            Tmp, X_Left, X_Right : out Integer);

end Colors;
```

Listing 22: test_reverse_colors.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Colors; use Colors;

procedure Test.Reverse.Colors is

    My_Colors : Color_Array (1 .. 5) :=
        (Black, Red, Green, Blue, White);

begin

    for C of My_Colors loop
        Put_Line ("My_Color: " & Color'Image (C));
    end loop;

    New_Line;
    Put_Line ("Reversing My_Color..."); New_Line;
    Reverse_It (My_Colors);

    for C of My_Colors loop
        Put_Line ("My_Color: " & Color'Image (C));
    end loop;

end Test.Reverse.Colors;
```

In the example above, package Colors implements the procedure Reverse_It by declaring new names for two positions of the array. The actual implementation becomes easy to read:
**Introduction to Ada**

```ada
begin
    Tmp := X_Left;
    X_Left := X_Right;
    X_Right := Tmp;
end;
```

Compare this to the alternative version without renaming:

```ada
begin
    Tmp := X (I);
    X (I) := X (X'Last + X'First - I);
    X (X'Last + X'First - I) := Tmp;
end;
```
8.1 Aggregates: A primer

So far, we have talked about aggregates quite a bit and have seen a number of examples. Now we will revisit this feature in some more detail.

An Ada aggregate is, in effect, a literal value for a composite type. It's a very powerful notation that helps you to avoid writing procedural code for the initialization of your data structures in many cases.

A basic rule when writing aggregates is that every component of the array or record has to be specified, even components that have a default value.

This means that the following code is incorrect:

Listing 1: incorrect.ads

```ada
package Incorrect is
  type Point is record
    X, Y : Integer := 0;
  end record;
  Origin : Point := (X => 0);
end Incorrect;
```

Code block metadata

Project: Courses.Intro_To_Ada.More_About_Types.Incorrect_Aggregate
MD5: 80a3475dece1c42cfb67b1d57b5bd464

Build output

incorrect.ads:6:22: error: no value supplied for component "Y"
gprbuild: *** compilation phase failed

There are a few shortcuts that you can use to make the notation more convenient:

- To specify the default value for a component, you can use the <> notation.
- You can use the | symbol to give several components the same value.
- You can use the others choice to refer to every component that has not yet been specified, provided all those fields have the same type.
- You can use the range notation .. to refer to specify a contiguous sequence of indices in an array.

However, note that as soon as you used a named association, all subsequent components likewise need to be specified with named associations.
### 8.2 Overloading and qualified expressions

Ada has a general concept of name overloading, which we saw earlier in the section on enumeration types (page 47).

Let's take a simple example: it is possible in Ada to have functions that have the same name, but different types for their parameters.

```ada
package Pkg is
  function F (A : Integer) return Integer;
  function F (A : Character) return Integer;
end Pkg;
```

This is a common concept in programming languages, called overloading\(^\text{(12)}\), or name overloading.

One of the novel aspects of Ada's overloading facility is the ability to resolve overloading based on the return type of a function.

```ada
package Pkg is
  type SSID is new Integer;
end Pkg;
```

\(^{12}\) [https://en.wikipedia.org/wiki/Function_overloading](https://en.wikipedia.org/wiki/Function_overloading)
function Convert (Self : SSID) return Integer;
function Convert (Self : SSID) return String;
end Pkg;

Listing 5: main.adb

with Ada.Text_IO; use Ada.Text_IO;
with Pkg; use Pkg;

procedure Main is
  S : String := Convert (123_145_299);
  -- ^ Valid, will choose the proper Convert
  begin
    Put_Line (S);
  end Main;

Code block metadata
Project: Courses.Intro_To_Ada.More_About_Types.Overloading
MD5: aa556b55ee89f9c5f8f7e138d84c27b8

Attention: Note that overload resolution based on the type is allowed for both functions and enumeration literals in Ada - which is why you can have multiple enumeration literals with the same name. Semantically, an enumeration literal is treated like a function that has no parameters.

However, sometimes an ambiguity makes it impossible to resolve which declaration of an overloaded name a given occurrence of the name refers to. This is where a qualified expression becomes useful.

Listing 6: pkg.ads

package Pkg is
type SSID is new Integer;

  function Convert (Self : SSID) return Integer;
  function Convert (Self : SSID) return String;
  function Convert (Self : Integer) return String;
end Pkg;

Listing 7: main.adb

with Ada.Text_IO; use Ada.Text_IO;
with Pkg; use Pkg;

procedure Main is
  S : String := Convert (123_145_299);
  -- ^ Invalid, which convert should we call?
  S2 : String := Convert (SSID' (123_145_299));

8.2. Overloading and qualified expressions
Code block metadata

Project: Courses.Intro_To_Ada.More_About_Types.Overloading_Error
MD5: 722660d8b692cde65a1c2b7800dd78c4

Syntactically the target of a qualified expression can be either any expression in parentheses, or an aggregate:

Listing 8: qual_expr.ads

```
package Qual_Expr is
  type Point is record
    A, B : Integer;
  end record;
  P : Point := Point' (12, 15);
  A : Integer := Integer' (12);
end Qual_Expr;
```

Code block metadata

Project: Courses.Intro_To_Ada.More_About_Types.Qual_Expr
MD5: e71523eb41a28a4f6549d5f8418620a

This illustrates that qualified expressions are a convenient (and sometimes necessary) way for the programmer to make the type of an expression explicit, for the compiler of course, but also for other programmers.

**Attention:** While they look and feel similar, type conversions and qualified expressions are not the same.

A qualified expression specifies the exact type that the target expression will be resolved to, whereas a type conversion will try to convert the target and issue a run-time error if the target value cannot be so converted.

Note that you can use a qualified expression to convert from one subtype to another, with an exception raised if a constraint is violated.

```
X : Integer := Natural'(1);
```
8.3 Character types

As noted earlier, each enumeration type is distinct and incompatible with every other enumeration type. However, what we did not mention previously is that character literals are permitted as enumeration literals. This means that in addition to the language's strongly typed character types, user-defined character types are also permitted:

Listing 9: character_example.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Character_Example is
  type My_Char is ('a', 'b', 'c');
  -- Our custom character type, an
  -- enumeration type with 3 valid values.

  C : Character;
  -- ^ Built-in character type
  -- (it's an enumeration type)

  M : My_Char;

begin
  C := '?';
  -- ^ Character literal
  -- (enumeration literal)

  M := 'a';

  C := 65;
  -- ^ Invalid: 65 is not a
  -- Character value

  C := Character’Val (65);
  -- Assign the character at
  -- position 65 in the
  -- enumeration (which is 'A')

  M := C;
  -- ^ Invalid: C is of type Character,
  -- and M is a My_Char

  M := 'd';
  -- ^ Invalid: 'd' is not a valid
  -- literal for type My_Char

end Character_Example;
```

In this example, we're using characters in the definition of My_Char.
9.1 Overview

Pointers are a potentially dangerous construct, which conflicts with Ada's underlying philosophy.

There are two ways in which Ada helps shield programmers from the dangers of pointers:

1. One approach, which we have already seen, is to provide alternative features so that the programmer does not need to use pointers. Parameter modes, arrays, and varying size types are all constructs that can replace typical pointer usages in C.

2. Second, Ada has made pointers as safe and restricted as possible, but allows "escape hatches" when the programmer explicitly requests them and presumably will be exercising such features with appropriate care.

Here is how you declare a simple pointer type, or access type, in Ada:

Listing 1: dates.ads

```ada
package Dates is
type Months is
  (January, February, March, April, May, June, July, August, September, October, November, December);
type Date is record
  Day : Integer range 1 .. 31;
  Month : Months;
  Year : Integer;
end record;
end Dates;
```

Listing 2: access_types.ads

```ada
with Dates; use Dates;
package Access_Types is
  -- Declare an access type
type Date_Acc is access Date;
  -- "Designated type"
  -- Date_Acc values
  -- point to Date objects
  D : Date_Acc := null;
  -- "Literal for
  -- access to nothing"
```

Introduction to Ada

(continued from previous page)

-- ^ Access to date

end Access_Types;

Code block metadata

Project: Courses.Intro_To_Ada.Access_Types.Access_Types
MD5: d3421918c48c221836bdf03b9e68bfb5

This illustrates how to:

• Declare an access type whose values point to ("designate") objects from a specific type
• Declare a variable (access value) from this access type
• Give it a value of null

In line with Ada's strong typing philosophy, if you declare a second access type whose designated type is Date, the two access types will be incompatible with each other:

Listing 3: access_types.ads

with Dates; use Dates;

package Access_Types is
  -- Declare an access type
type Date_Acc is access Date;
type Date_Acc_2 is access Date;
  D : Date_Acc := null;
  D2 : Date_Acc_2 := D;
  -- ^ Invalid! Different types
end Access_Types;

Code block metadata

Project: Courses.Intro_To_Ada.Access_Types.Access_Types
MD5: af0dff5a26cb16f0fe15c84286557a44

Build output

access_types.ads:9:24: error: expected type "Date_Acc_2" defined at line 6
access_types.ads:9:24: error: found type "Date_Acc" defined at line 5
gprbuild: *** compilation phase failed

In other languages

In most other languages, pointer types are structurally, not nominally typed, like they are in Ada, which means that two pointer types will be the same as long as they share the same target type and accessibility rules.

Not so in Ada, which takes some time getting used to. A seemingly simple problem is, if you want to have a canonical access to a type, where should it be declared? A commonly used pattern is that if you need an access type to a specific type you "own", you will declare it along with the type:

package Access_Types is
type Point is record
  X, Y : Natural;
end record;

(continues on next page)
9.2 Allocation (by type)

Once we have declared an access type, we need a way to give variables of the types a meaningful value! You can allocate a value of an access type with the new keyword in Ada.

```ada
with Dates; use Dates;
package Access_Types is
  type Date_Acc is access Date;
  D : Date_Acc := new Date;
end Access_Types;
```

If the type you want to allocate needs constraints, you can put them in the subtype indication, just as you would do in a variable declaration:

```ada
with Dates; use Dates;
package Access_Types is
  type String_Acc is access String;
  -- ^ Access to unconstrained array type
  Msg : String_Acc;
  -- ^ Default value is null
  Buffer : String_Acc :=
    new String (1..10);
  -- ^ Constraint required
end Access_Types;
```

In some cases, though, allocating just by specifying the type is not ideal, so Ada also allows you to initialize along with the allocation. This is done via the qualified expression syntax:

```ada
with Dates; use Dates;
package Access_Types is
  type Point_Access is access Point;
end Access_Types;
```

```ada
(continues on next page)
```
9.3 Dereferencing

The last important piece of Ada's access type facility is how to get from an access value to the object that is pointed to, that is, how to dereference the pointer. Dereferencing a pointer uses the `.all` syntax in Ada, but is often not needed — in many cases, the access value will be implicitly dereferenced for you:

```ada
with Dates; use Dates;
package Access_Types is
    type Date_Acc is access Date;
    D : Date_Acc := new Date'(30, November, 2011);
    Msg : String_Acc := new String"Hello");
end Access_Types;
```

Listing 7: access_types.ads

Code block metadata

Project: Courses.Intro_To_Ada.Access_Types.Access_Types
MD5: 5cd1c259da04010b0dc1b43e9bd93b55

9.4 Other features

As you might know if you have used pointers in C or C++, we are still missing features that are considered fundamental to the use of pointers, such as:

- Pointer arithmetic (being able to increment or decrement a pointer in order to point to the next or previous object)
- Manual deallocation - what is called free or delete in C. This is a potentially unsafe operation. To keep within the realm of safe Ada, you need to never deallocate manually.

Those features exist in Ada, but are only available through specific standard library APIs.

Attention: The guideline in Ada is that most of the time you can avoid manual allocation, and you should.
There are many ways to avoid manual allocation, some of which have been covered (such as parameter modes). The language also provides library abstractions to avoid pointers:

1. One is the use of containers (page 199). Containers help users avoid pointers, because container memory is automatically managed.

2. A container to note in this context is the Indefinite holder\(^\text{13}\) This container allows you to store a value of an indefinite type such as String.

3. GNATCOLL has a library for smart pointers, called Refcount\(^\text{14}\) Those pointers’ memory is automatically managed, so that when an allocated object has no more references to it, the memory is automatically deallocated.

### 9.5 Mutually recursive types

The linked list is a common idiom in data structures; in Ada this would be most naturally defined through two types, a record type and an access type, that are mutually dependent. To declare mutually dependent types, you can use an incomplete type declaration:

```ada
package Simple_List is
  type Node; -- This is an incomplete type declaration, which is completed in the same declarative region.
  type Node_Acc is access Node;
  type Node is record
    Content : Natural;
    Prev, Next : Node_Acc;
  end record;
end Simple_List;
```

In this example, the Node and Node_Acc types are mutually dependent.

\(^\text{13}\) http://www.ada-auth.org/standards/12rat/html/Rat12-8-5.html
\(^\text{14}\) https://github.com/AdaCore/gnatcoll-core/blob/master/src/gnatcoll-refcount.ads
10.1 Dynamically sized record types

We have previously seen some simple examples of record types (page 61). Let's now look at some of the more advanced properties of this fundamental language feature.

One point to note is that object size for a record type does not need to be known at compile time. This is illustrated in the example below:

Listing 1: runtime_length.ads

```ada
package Runtime_Length is
  function Compute_Max_Len return Natural;
end Runtime_Length;
```

Listing 2: var_size_record.ads

```ada
with Runtime_Length; use Runtime_Length;

package Var_Size_Record is
  Max.Len : constant Natural := Compute_Max_Len;
  -- ^ Not known at compile time

  type Items_Array is
    array (Positive range <>) of Integer;

  type Growable_Stack is record
    Items : Items_Array (1 .. Max.Len);
    Len : Natural;
  end record;
  -- Growable_Stack is a definite type, but
  -- size is not known at compile time.

  G : Growable_Stack;
end Var_Size_Record;
```

Code block metadata

Project: Courses.Intro_To_Ada.More_About_Records.Var_Size_Record
MD5: 6fb0b3f2b685a72ec694640ce378f77c

It is completely fine to determine the size of your records at run time, but note that all objects of this type will have the same size.
10.2 Records with discriminant

In the example above, the size of the Items field is determined once, at run-time, but every Growable_Stack instance will be exactly the same size. But maybe that’s not what you want to do. We saw that arrays in general offer this flexibility: for an unconstrained array type, different objects can have different sizes.

You can get analogous functionality for records, too, using a special kind of field that is called a discriminant:

```ada
package Var_Size_Record_2 is
type Items_Array is
  array (Positive range <>) of Integer;

type Growable_Stack (Max_Len : Natural) is
  record
    -- ^ Discriminant. Cannot be
    -- modified once
    -- initialized.
    Items : Items_Array (1 .. Max_Len);
    Len : Natural := 0;
  end record;
end Var_Size_Record_2;
```

Discriminants, in their simple forms, are constant: You cannot modify them once you have initialized the object. This intuitively makes sense since they determine the size of the object.

Also, they make a type indefinite: Whether or not the discriminant is used to specify the size of an object, a type with a discriminant will be indefinite if the discriminant is not declared with an initialization:

```ada
package Test_Discriminants is
  type Point (X, Y : Natural) is record
    null;
  end record;

  P : Point;
  -- ERROR: Point is indefinite, so you
  -- need to specify the discriminants
  -- or give a default value
  P2 : Point (1, 2);
  P3 : Point := (1, 2);
  -- Those two declarations are equivalent.
end Test_Discriminants;
```
Build output

test_discriminants.ads:6:08: error: unconstrained subtype not allowed (need initialization)
test_discriminants.ads:6:08: error: provide initial value or explicit discriminant values

test_discriminants.ads:6:08: error: or give default discriminant values for type "Point"
gprbuild: *** compilation phase failed

This also means that, in the example above, you cannot declare an array of Point values, because the size of a Point is not known.

As mentioned in the example above, we could provide a default value for the discriminants, so that we could legally declare Point values without specifying the discriminants. For the example above, this is how it would look:

Listing 5: test_discriminants.ads

```ada
package Test_Discriminants is
  type Point (X, Y : Natural := 0) is record
    null;
  end record;

  P : Point;
  -- We can now simply declare a "Point"
  -- without further ado. In this case,
  -- we're using the default values (0)
  -- for X and Y.

  P2 : Point (1, 2);
  P3 : Point := (1, 2);
  -- We can still specify discriminants.
end Test_Discriminants;
```

Code block metadata

Project: Courses.Intro_To_Ada.More_About_Records.Test_Discriminants
MD5: c3ec81ccae0d4144fe952ad99482be81

Also note that, even though the Point type now has default discriminants, we can still specify discriminants, as we're doing in the declarations of P2 and P3.

In most other respects discriminants behave like regular fields: You have to specify their values in aggregates, as seen above, and you can access their values via the dot notation.

Listing 6: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Var_Size_Record_2; use Var_Size_Record_2;

procedure Main is
  procedure Print_Stack (G : Growable_Stack) is
    begin
    Put ("<Stack, items: [";
      for I in G.Items'Range loop
        exit when I > G.Len;
```

(continues on next page)
### 10.3 Variant records

The examples of discriminants thus far have illustrated the declaration of records of varying size, by having components whose size depends on the discriminant.

However, discriminants can also be used to obtain the functionality of what are sometimes called "variant records": records that can contain different sets of fields.

```
package Variant_Record is
  -- Forward declaration of Expr
  type Expr;

  -- Access to a Expr
  type Expr_Access is access Expr;

  type Expr_Kind_Type is (Bin.Op_Plus,
                           Bin.Op_Minus,
                           Num);

  -- A regular enumeration type
  type Expr (Kind : Expr_Kind_Type) is record
    -- ^ The discriminant is an
    -- enumeration value
    case Kind is
        Left, Right : Expr_Access;
      when Num =>
        Val : Integer;
  end record;
```

Note: In the examples above, we used a discriminant to determine the size of an array, but it is not limited to that, and could be used, for example, to determine the size of a nested discriminated record.
end case;
-- Variant part. Only one, at the end of
-- the record definition, but can be
-- nested
end record;
end Variant_Record;

The fields that are in a when branch will be only available when the value of the discriminant is covered by the branch. In the example above, you will only be able to access the fields Left and Right when the Kind is Bin_Op_Plus or Bin_Op_Minus.

If you try to access a field that is not valid for your record, a Constraint_Error will be raised.

Listing 8: main.adb

with Variant_Record; use Variant_Record;

procedure Main is
  E : Expr := (Num, 12);
begin
  E.Left := new Expr'(Num, 15);
  -- Will compile but fail at runtime
end Main;

Here is how you could write an evaluator for expressions:

Listing 9: main.adb

with Ada.Text_IO; use Ada.Text_IO;
with Variant_Record; use Variant_Record;

procedure Main is
  function Eval_Expr (E : Expr) return Integer is
    (case E.Kind is
     when Bin_Op_Plus =>
      Eval_Expr (E.Left.all)
         + Eval_Expr (E.Right.all),
     -- ...
    end case;

10.3. Variant records
In other languages

Ada's variant records are very similar to Sum types in functional languages such as OCaml or Haskell. A major difference is that the discriminant is a separate field in Ada, whereas the 'tag' of a Sum type is kind of built in, and only accessible with pattern matching.

There are other differences (you can have several discriminants in a variant record in Ada). Nevertheless, they allow the same kind of type modeling as sum types in functional languages.

Compared to C/C++ unions, Ada variant records are more powerful in what they allow, and are also checked at run time, which makes them safer.
11.1 Decimal fixed-point types

We have already seen how to specify floating-point types. However, in some applications
floating-point is not appropriate since, for example, the roundoff error from binary arith-
metic may be unacceptable or perhaps the hardware does not support floating-point in-
structions. Ada provides a category of types, the decimal fixed-point types, that allows the
programmer to specify the required decimal precision (number of digits) as well as the scal-
ing factor (a power of ten) and, optionally, a range. In effect the values will be represented
as integers implicitly scaled by the specified power of 10. This is useful, for example, for
financial applications.

The syntax for a simple decimal fixed-point type is

```
type <type-name> is delta <delta-value> digits <digits-value>;
```

In this case, the `delta` and the `digits` will be used by the compiler to derive a range.

Several attributes are useful for dealing with decimal types:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>First</td>
<td>The first value of the type</td>
</tr>
<tr>
<td>Last</td>
<td>The last value of the type</td>
</tr>
<tr>
<td>Delta</td>
<td>The delta value of the type</td>
</tr>
</tbody>
</table>

In the example below, we declare two data types: T3_D3 and T6_D3. For both types, the
delta value is the same: 0.001.

Listing 1: decimal_fixed_point_types.adb

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Decimal_Fixed_Point_Types is
  type T3_D3 is delta 10.0 ** (-3) digits 3;
  type T6_D3 is delta 10.0 ** (-3) digits 6;
  begin
    Put_Line ("The delta value of T3_D3 is "
      & T3_D3'Image (T3_D3'Delta));
    Put_Line ("The minimum value of T3_D3 is "
      & T3_D3'Image (T3_D3'First));
    Put_Line ("The maximum value of T3_D3 is "
      & T3_D3'Image (T3_D3'Last));
    New_Line;
    Put_Line ("The delta value of T6_D3 is "
      & T6_D3'Image (T6_D3'Delta));
```

(continues on next page)
Put_Line ("The minimum value of T6_D3 is \
& T6_D3’Image (T6_D3’First));
Put_Line ("The maximum value of T6_D3 is \
& T6_D3’Image (T6_D3’Last));
end Decimal_Fixed_Point_Types;

Code block metadata
Project: Courses.Intro_To_Ada.Fixed_Point_Types.Decimal_Fixed_Point_Types
MD5: 6b1f6bfa555031b831aa872187c8bee9

Runtime output
The delta value of T3_D3 is 0.001
The minimum value of T3_D3 is -0.999
The maximum value of T3_D3 is 0.999
The delta value of T6_D3 is 0.001
The minimum value of T6_D3 is -999.999
The maximum value of T6_D3 is 999.999

When running the application, we see that the delta value of both types is indeed the same: 0.001. However, because T3_D3 is restricted to 3 digits, its range is -0.999 to 0.999. For the T6_D3, we have defined a precision of 6 digits, so the range is -999.999 to 999.999.

Similar to the type definition using the range syntax, because we have an implicit range, the compiled code will check that the variables contain values that are not out-of-range. Also, if the result of a multiplication or division on decimal fixed-point types is smaller than the delta value required for the context, the actual result will be zero. For example:

Listing 2: decimal_fixed_point_smaller.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Decimal_Fixed_Point_Smaller is
  type T3_D3 is delta 10.0 ** (-3) digits 3;
  type T6_D6 is delta 10.0 ** (-6) digits 6;
  A : T3_D3 := T3_D3’Delta;
  B : T3_D3 := 0.5;
  C : T6_D6;
begin
  Put_Line ("The value of A is " \
& T3_D3’Image (A));
  A := A * B;
  Put_Line ("The value of A * B is " \
& T3_D3’Image (A));
  A := T3_D3’Delta;
  C := A * B;
  Put_Line ("The value of A * B is " \
& T6_D6’Image (C));
end Decimal_Fixed_Point_Smaller;

Code block metadata
Project: Courses.Intro_To_Ada.Fixed_Point_Types.Decimal_Fixed_Point_Smaller
MD5: 6b0242caa4a79f9b3447a304002e6a3b

Runtime output
The value of A is 0.001
The value of A * B is 0.000
The value of A * B is 0.000500

In this example, the result of the operation 0.001 * 0.5 is 0.0005. Since this value is not representable for the T3.D3 type because the delta value is 0.001, the actual value stored in variable A is zero. However, accuracy is preserved during the arithmetic operations if the target has sufficient precision, and the value displayed for C is 0.000500.

11.2 Ordinary fixed-point types

Ordinary fixed-point types are similar to decimal fixed-point types in that the values are, in effect, scaled integers. The difference between them is in the scale factor: for a decimal fixed-point type, the scaling, given explicitly by the type's delta, is always a power of ten.

In contrast, for an ordinary fixed-point type, the scaling is defined by the type's small, which is derived from the specified delta and, by default, is a power of two. Therefore, ordinary fixed-point types are sometimes called binary fixed-point types.

**Note:** Ordinary fixed-point types can be thought of being closer to the actual representation on the machine, since hardware support for decimal fixed-point arithmetic is not widespread (rescalings by a power of ten), while ordinary fixed-point types make use of the available integer shift instructions.

The syntax for an ordinary fixed-point type is

```ada
type <type-name> is
delta <delta-value>
range <lower-bound> .. <upper-bound>;
```

By default the compiler will choose a scale factor, or small, that is a power of 2 no greater than <delta-value>.

For example, we may define a normalized range between -1.0 and 1.0 as following:

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Normalized_FIXED_Point_Type is
  D : constant := 2.0 ** (-31);
  type TQ31 is delta D range -1.0 .. 1.0 - D;
begin
  Put_Line ("TQ31 requires "
              & Integer'Image (TQ31'Size)
              & " bits");
  Put_Line ("The delta value of TQ31 is "
              & TQ31'Delta);
  Put_Line ("The minimum value of TQ31 is "
              & TQ31'First);
  Put_Line ("The maximum value of TQ31 is "
              & TQ31'Last);
end Normalized_FIXED_Point_Type;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Fixed_Point_Types.Normalized_FIXED_Point_Type

MD5: 778dde401c7ff3dd42938dccfe6cf9d3

11.2. Ordinary fixed-point types
Introduction to Ada

Runtime output

TQ31 requires 32 bits
The delta value of TQ31 is 0.0000000005
The minimum value of TQ31 is -1.0000000000
The maximum value of TQ31 is 0.9999999995

In this example, we are defining a 32-bit fixed-point data type for our normalized range. When running the application, we notice that the upper bound is close to one, but not exact one. This is a typical effect of fixed-point data types — you can find more details in this discussion about the Q format\(^5\).

We may also rewrite this code with an exact type definition:

Listing 4: normalized_adapted_fixed_point_type.adb

```ada
procedure Normalized_Adapted_Fixed_Point_Type is
type TQ31 is
  delta 2.0 ** (-31)
  range -1.0 .. 1.0 - 2.0 ** (-31);
begin
  null;
end Normalized_Adapted_Fixed_Point_Type;
```

We may also use any other range. For example:

Listing 5: custom_fixed_point_range.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Numerics; use Ada.Numerics;

procedure Custom_Fixed_Point_Range is
type T_Inv_Trig is
  delta 2.0 ** (-15) * Pi
  range -Pi / 2.0 .. Pi / 2.0;
begin
  Put_Line ("T_Inv_Trig requires 
            & Integer'Image (T_Inv_Trig'Size)
            & " bits");
  Put_Line ("Delta value of T_Inv_Trig: 
            & T_Inv_Trig'Delta");
  Put_Line ("Minimum value of T_Inv_Trig: 
            & T_Inv_Trig'First");
  Put_Line ("Maximum value of T_Inv_Trig: 
            & T_Inv_Trig'Last");
end Custom_Fixed_Point_Range;
```

Runtime output

\(^5\) https://en.wikipedia.org/wiki/Q_(number_format)
Introduction to Ada

T_Inv_Trig requires 16 bits
Delta value of T_Inv_Trig: 0.00006
Minimum value of T_Inv_Trig: -1.57080
Maximum value of T_Inv_Trig: 1.57080

In this example, we are defining a 16-bit type called T_Inv_Trig, which has a range from \(-\pi/2\) to \(\pi/2\).

All standard operations are available for fixed-point types. For example:

Listing 6: fixed_point_op.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Fixed_Point_Op is
  type TQ31 is
    delta 2.0 ** (-31)
    range -1.0 .. 1.0 - 2.0 ** (-31);
  A, B, R : TQ31;
begin
  A := 0.25;
  B := 0.50;
  R := A + B;
  Put_Line ("R is " & TQ31'Image (R));
end Fixed_Point_Op;
```

As expected, \(R\) contains 0.75 after the addition of \(A\) and \(B\).

In fact the language is more general than these examples imply, since in practice it is typical to need to multiply or divide values from different fixed-point types, and obtain a result that may be of a third fixed-point type. The details are outside the scope of this introductory course.

It is also worth noting, although again the details are outside the scope of this course, that you can explicitly specify a value for an ordinary fixed-point type's small. This allows non-binary scaling, for example:

```ada
type Angle is
  delta 1.0/3600.0
  range 0.0 .. 360.0 - 1.0 / 3600.0;
for Angle'Small use Angle'Delta;
```

11.2. Ordinary fixed-point types
One of the main principles of modular programming, as well as object oriented programming, is **encapsulation**.

Encapsulation, briefly, is the concept that the implementer of a piece of software will distinguish between the code's public interface and its private implementation.

This is not only applicable to software libraries but wherever abstraction is used.

In Ada, the granularity of encapsulation is a bit different from most object-oriented languages, because privacy is generally specified at the package level.

### 12.1 Basic encapsulation

**Listing 1: encapsulate.ads**

```ada
package Encapsulate is

procedure Hello;

private

procedure Hello2;

-- Not visible from external units
end Encapsulate;
```

**Listing 2: encapsulate.adb**

```ada
with Ada.Text_IO; use Ada.Text_IO;

package body Encapsulate is

procedure Hello is

begin

Put_Line ("Hello");
end Hello;

procedure Hello2 is

begin

Put_Line ("Hello #2");
end Hello2;

end Encapsulate;
```

---

16 https://en.wikipedia.org/wiki/Encapsulation_(computer_programming)
**Introduction to Ada**

**Listing 3: main.adb**

```ada
with Encapsulate;

procedure Main is
begin
  Encapsulate.Hello;
  Encapsulate.Hello2;
  -- Invalid: Hello2 is not visible
end Main;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Privacy.Encapsulate
MD5: cf56ee89481962d1e0a6d1e9ad888362

**Build output**

main.adb:6:15: error: "Hello2" is not a visible entity of "Encapsulate"
gprbuild: *** compilation phase failed

### 12.2 Abstract data types

With this high-level granularity, it might not seem obvious how to hide the implementation details of a type. Here is how it can be done in Ada:

**Listing 4: stacks.ads**

```ada
package Stacks is
  type Stack is private;
  -- Declare a private type: You cannot depend
  -- on its implementation. You can only assign
  -- and test for equality.

  procedure Push (S : in out Stack; Val : Integer);
  procedure Pop (S : in out Stack; Val : out Integer);

private

  subtype Stack_Index is
    Natural range 1 .. 10;

  type Content_Type is
    array (Stack_Index) of Natural;

  type Stack is record
    Top : Stack_Index;
    Content : Content_Type;
  end record;

end Stacks;
```

**Listing 5: stacks.adb**

```ada
package body Stacks is

  procedure Push (S : in out Stack; Val : Integer) is
```

(continues on next page)
In the above example, we define a stack type in the public part (known as the visible part of the package spec in Ada), but the exact representation of that type is private.

Then, in the private part, we define the representation of that type. We can also declare other types that will be used as helpers for our main public type. This is useful since declaring helper types is common in Ada.

A few words about terminology:

- The Stack type as viewed from the public part is called the partial view of the type. This is what clients have access to.
- The Stack type as viewed from the private part or the body of the package is called the full view of the type. This is what implementers have access to.

From the point of view of the client (the with'ing unit), only the public (visible) part is important, and the private part could as well not exist. It makes it very easy to read linearly the part of the package that is important for you.

```
package Stacks is
  type Stack is private;
  procedure Push (S : in out Stack; Val : Integer);
  procedure Pop (S : in out Stack; Val : out Integer);
private
  ...
end Stacks;
```

Here is how the Stacks package would be used:

```
-- Example of use
with Stacks; use Stacks;

procedure Test_Stack is
  S : Stack;
  Res : Integer;
begin
  Push (S, 5);
  Push (S, 7);
  Pop (S, Res);
end Test_Stack;
```

12.2. Abstract data types
12.3 Limited types

Ada's *limited type* facility allows you to declare a type for which assignment and comparison operations are not automatically provided.

Listing 6: stacks.ads

```ada
package Stacks is
  type Stack is limited private;
    -- Limited type. Cannot assign nor compare.
    procedure Push (S : in out Stack;
      Val :    Integer);
    procedure Pop (S : in out Stack;
      Val :    out Integer);
private
    subtype Stack_Index is
      Natural range 1 .. 10;

    type Content_Type is
      array (Stack_Index) of Natural;

type Stack is limited record
  Top : Stack_Index;
  Content : Content_Type;
end record;
end Stacks;
```

Listing 7: stacks.adb

```ada
package body Stacks is
  procedure Push (S : in out Stack;
    Val :    Integer) is
  begin
    null;
  end Push;

  procedure Pop (S : in out Stack;
    Val :    out Integer) is
  begin
    Val := 0;
  end Pop;
end Stacks;
```
Listing 8: main.adb

```ada
with Stacks; use Stacks;

procedure Main is
  S, S2 : Stack;
begin
  S := S2;
  -- Illegal: S is limited.
end Main;
```

## Code block metadata

- **Project:** Courses.Intro_To_Ada.Privacy.Limited_Stacks
- **MD5:** 811343b46f20ac6af5e1bf26561f8d8d

### Build output

```
main.adb:6:04: error: left hand of assignment must not be limited type
gprbuild: *** compilation phase failed
```

This is useful because, for example, for some data types the built-in assignment operation might be incorrect (for example when a deep copy is required).

Ada does allow you to overload the comparison operators = and /= for limited types (and to override the built-in declarations for non-limited types).

Ada also allows you to implement special semantics for assignment via controlled types\(^\text{17}\). However, in some cases assignment is simply inappropriate; one example is the `File_Type` from the Ada.Text_IO package, which is declared as a limited type and thus attempts to assign one file to another would be detected as illegal.

### 12.4 Child packages & privacy

We've seen previously (in the child packages section (page 35)) that packages can have child packages. Privacy plays an important role in child packages. This section discusses some of the privacy rules that apply to child packages.

Although the private part of a package \(P\) is meant to encapsulate information, certain parts of a child package \(P.C\) can have access to this private part of \(P\). In those cases, information from the private part of \(P\) can then be used as if it were declared in the public part of its specification. To be more specific, the body of \(P.C\) and the private part of the specification of \(P.C\) have access to the private part of \(P\). However, the public part of the specification of \(P.C\) only has access to the public part of \(P\)'s specification. The following table summarizes this:

<table>
<thead>
<tr>
<th>Part of a child package</th>
<th>Access to the private part of its parent's specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specification: public part</td>
<td>[ ]</td>
</tr>
<tr>
<td>Specification: private part</td>
<td>✓</td>
</tr>
<tr>
<td>Body</td>
<td>✓</td>
</tr>
</tbody>
</table>

The rest of this section shows examples of how this access to private information actually works for child packages.

Let's first look at an example where the body of a child package \(P.C\) has access to the private part of the specification of its parent \(P\). We've seen, in a previous source-code example,

\(^\text{17}\) [http://www.ada-auth.org/standards/12rm/html/RM-7-6.html](http://www.ada-auth.org/standards/12rm/html/RM-7-6.html)
that the Hello2 procedure declared in the private part of the Encapsulate package cannot be used in the Main procedure, since it’s not visible there. This limitation doesn’t apply, however, for parts of the child packages of the Encapsulate package. In fact, the body of its child package Encapsulate.Child has access to the Hello2 procedure and can call it there, as you can see in the implementation of the Hello3 procedure of the Child package:

Listing 9: encapsulate.ads

```ada
package Encapsulate is
  procedure Hello;

private

  procedure Hello2;
  -- Not visible from external units
  -- But visible in child packages
end Encapsulate;
```

Listing 10: encapsulate.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

package body Encapsulate is

  procedure Hello is
    begin
      Put_Line ("Hello");
    end Hello;

  procedure Hello2 is
    begin
      Put_Line ("Hello #2");
    end Hello2;

end Encapsulate;
```

Listing 11: encapsulate-child.ads

```ada
package Encapsulate.Child is

  procedure Hello3;

end Encapsulate.Child;
```

Listing 12: encapsulate-child.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

package body Encapsulate.Child is

  procedure Hello3 is
    begin
      -- Using private procedure Hello2
      -- from the parent package
      Hello2;
      Put_Line ("Hello #3");
    end Hello3;

end Encapsulate.Child;
```
with Encapsulate.Child;

procedure Main is
begin
  Encapsulate.Child.Hello3;
end Main;

Code block metadata

Project: Courses.Intro_To_Ada.Privacy.Encapsulate_Child
MD5: 1533f43eee8f8b4d14c9b2101f42f13a

Runtime output
Hello #2
Hello #3

The same mechanism applies to types declared in the private part of a parent package. For
instance, the body of a child package can access components of a record declared in the
private part of its parent package. Let’s look at an example:

Listing 14: my_types.ads

package My_Types is
  type Priv Rec is private;

private

  type Priv Rec is record
    Number : Integer := 42;
  end record;

end My_Types;

Listing 15: my_types-ops.ads

package My_Types.Ops is
  procedure Display (E : Priv Rec);
end My_Types.Ops;

Listing 16: my_types-ops.adb

with Ada.Text_IO; use Ada.Text_IO;

package body My_Types.Ops is
  procedure Display (E : Priv Rec) is
    begin
      Put_Line ("Priv Rec.Number: ",
                & Integer'Image (E.Number));
    end Display;
end My_Types.Ops;
Listing 17: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with My_Types; use My_Types;
with My_Types.Ops; use My_Types.Ops;

procedure Main is
  E : Priv_Rec;
begin
  Put_Line ("Presenting information: ");
  -- The following code would trigger a
  -- compilation error here:
  --
  -- Put_Line ("Priv_Rec.Number: 
  -- & Integer'Image (E.Number));
  Display (E);
end Main;
```

Code block metadata

Project: Courses.Intro_To_Ada.Privacy.Private_Type_Child
MD5: 9960611460bc1190b30949eca08fc02b

Runtime output

**Presenting information:**

Priv_Rec.Number:  42

In this example, we don't have access to the Number component of the record type Priv_Rec in the Main procedure. You can see this in the call to Put_Line that has been commented-out in the implementation of Main. Trying to access the Number component there would trigger a compilation error. But we do have access to this component in the body of the My_Types.Ops package, since it's a child package of the My_Types package. Therefore, Ops's body has access to the declaration of the Priv_Rec type — which is in the private part of its parent, the My_Types package. For this reason, the same call to Put_Line that would trigger a compilation error in the Main procedure works fine in the Display procedure of the My_Types.Ops package.

This kind of privacy rules for child packages allows for extending the functionality of a parent package and, at the same time, retain its encapsulation.

As we mentioned previously, in addition to the package body, the private part of the specification of a child package P.C also has access to the private part of the specification of its parent P. Let's look at an example where we declare an object of private type Priv_Rec in the private part of the child package My_Types.Child and initialize the Number component of the Priv_Rec record directly:

```ada
package My_Types.Child is
private
  E : Priv_Rec := (Number => 99);
end My_Types.Ops;
```

As expected, we wouldn't be able to initialize this component if we moved this declaration to the public (visible) part of the same child package:
package My_Types.Child is

   E : Priv_Rec := (Number => 99);

end My_Types.Ops;

The declaration above triggers a compilation error, since type Priv_Rec is private. Because the public part of My_Types.Child is also visible outside the child package, Ada cannot allow accessing private information in this part of the specification.
13.1 Introduction

Generics are used for metaprogramming in Ada. They are useful for abstract algorithms that share common properties with each other.

Either a subprogram or a package can be generic. A generic is declared by using the keyword `generic`. For example:

Listing 1: operator.ads

```
generic
  type T is private;
  -- Declaration of formal types and objects
  -- Below, we could use one of the following:
  -- <procedure | function | package>
  procedure Operator (Dummy : in out T);
```

Listing 2: operator.adb

```
procedure Operator (Dummy : in out T) is
begin
  null;
end Operator;
```

13.2 Formal type declaration

Formal types are abstractions of a specific type. For example, we may want to create an algorithm that works on any integer type, or even on any type at all, whether a numeric type or not. The following example declares a formal type T for the Set procedure.

Listing 3: set.ads

```
generic
  type T is private;
  -- T is a formal type that indicates that
  -- any type can be used, possibly a numeric
  -- type or possibly even a record type.
  procedure Set (Dummy : T);
```
The declaration of T as **private** indicates that you can map any definite type to it. But you can also restrict the declaration to allow only some types to be mapped to that formal type. Here are some examples:

<table>
<thead>
<tr>
<th>Formal Type</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any type</td>
<td><code>type T is private;</code></td>
</tr>
<tr>
<td>Any discrete type</td>
<td><code>type T is (&lt;&gt;);</code></td>
</tr>
<tr>
<td>Any floating-point type</td>
<td><code>type T is digits &lt;&gt;;</code></td>
</tr>
</tbody>
</table>

**13.3 Formal object declaration**

Formal objects are similar to subprogram parameters. They can reference formal types declared in the formal specification. For example:

Listing 5: set.ads

```ada
generic
    type T is private;
    X : in out T;
-- X can be used in the Set procedure
procedure Set (E : T);
```
procedure Set (E : T) is  
pragma Unreferenced (E, X);  
begin  
   null;  
end Set;

13.4 Generic body definition

We don't repeat the generic keyword for the body declaration of a generic subprogram or package. Instead, we start with the actual declaration and use the generic types and objects we declared. For example:

Listing 7: set.ads

generic  
   type T is private;  
   X : in out T;  
procedure Set (E : T);

Listing 8: set.adb

procedure Set (E : T) is  
-- Body definition: "generic" keyword  
-- is not used  
begin  
   X := E;  
end Set;

13.5 Generic instantiation

Generic subprograms or packages can't be used directly. Instead, they need to be instantiated, which we do using the new keyword, as shown in the following example:

Listing 9: set.ads

generic  
   type T is private;  
   X : in out T;  
   -- X can be used in the Set procedure  
procedure Set (E : T);
Introduction to Ada

Listing 10: set.adb

```ada
procedure Set (E : T) is
begin
  X := E;
end Set;
```

Listing 11: show_generic_instantiation.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Set;

procedure Show_Generic_Instantiation is
  Main   : Integer := 0;
  Current: Integer;

  procedure Set_Main is new Set (T => Integer,
                                X => Main);

  -- Here, we map the formal parameters to
  -- actual types and objects.
  --
  -- The same approach can be used to
  -- instantiate functions or packages, e.g.:
  --
  -- function Get_Main is new ...
  -- package IntegerQueue is new ...

begin
  Current := 10;
  Set_Main (Current);
  Put_Line ("Value of Main is "
            & Integer'Image (Main));
end Show_Generic_Instantiation;
```

Code block metadata

Project: Courses.Intro_To_Ada.Generics.Show_Generic_Instantiation
MD5: 13dc0692252496d954240952561e1c05

Runtime output

Value of Main is 10

In the example above, we instantiate the procedure Set by mapping the formal parameters T and X to actual existing elements, in this case the Integer type and the Main variable.

13.6 Generic packages

The previous examples focused on generic subprograms. In this section, we look at generic packages. The syntax is similar to that used for generic subprograms: we start with the generic keyword and continue with formal declarations. The only difference is that package is specified instead of a subprogram keyword.

Here's an example:
Introduction to Ada

Listing 12: element.ads

generic
    type T is private;
package Element is
    procedure Set (E : T);
    procedure Reset;
    function Get return T;
    function Is_Valid return Boolean;
    Invalid_Element : exception;
private
    Value : T;
    Valid : Boolean := False;
end Element;

Listing 13: element.adb

package body Element is
    procedure Set (E : T) is
    begin
        Value := E;
        Valid := True;
    end Set;
    procedure Reset is
    begin
        Valid := False;
    end Reset;
    function Get return T is
    begin
        if not Valid then
            raise Invalid_Element;
        end if;
        return Value;
    end Get;
    function Is_Valid return Boolean is (Valid);
end Element;

Listing 14: show_generic_package.adb

with Ada.Text_IO; use Ada.Text_IO;
with Element;

procedure Show_Generic_Package is
    package I is new Element (T => Integer);
    procedure Display_INITIALIZED is
    begin
        if I.Is_Valid then
            Put_Line ("Value is initialized");
        else
            Put_Line ("Value is not initialized");
        end if;
    end Display_INITIALIZED;

(continues on next page)
In the example above, we created a simple container named Element, with just one single element. This container tracks whether the element has been initialized or not.

After writing the package definition, we create the instance I of the Element. We use the instance by calling the package subprograms (Set, Reset, and Get).

### 13.7 Formal subprograms

In addition to formal types and objects, we can also declare formal subprograms or packages. This course only describes formal subprograms; formal packages are discussed in the advanced course.

We use the `with` keyword to declare a formal subprogram. In the example below, we declare a formal function (Comparison) to be used by the generic procedure Check.

#### Listing 15: check.ads

```ada
generic
    Description : String;
    type T is private;
    with function Comparison (X, Y : T)
        return Boolean;
procedure Check (X, Y : T);
```

#### Listing 16: check.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
```
procedure Check (X, Y : T) is
  Result : Boolean;
begin
  Result := Comparison (X, Y);
  if Result then
    Put_Line
      ("Comparison (" & Description & ") between arguments is OK!");
  else
    Put_Line
      ("Comparison (" & Description & ") between arguments is not OK!");
  end if;
end Check;

Listing 17: show_formal_subprogram.adb

with Check;

procedure Show_Formal_Subprogram is
  A, B : Integer;

  procedure Check_Is_Equal is new Check (Description => "equality",
                                         T => Integer,
                                         Comparison => Standard."=");
  begin
    A := 0;
    B := 1;
    Check_Is_Equal (A, B);
  end Show_Formal_Subprogram;

Code block metadata

Project: Courses.Intro_To_Ada.Generics.Show_Formal_Subprogram
MD5: 1c463a47e9ce56b5afbcda6acdl6d

Runtime output

Comparison (equality) between arguments is not OK!

13.8 Example: I/O instances

Ada offers generic I/O packages that can be instantiated for standard and derived types. One example is the generic Float_IO package, which provides procedures such as Put and Get. In fact, Float_Text_IO — available from the standard library — is an instance of the Float_IO package, and it’s defined as:

with Ada.Text_IO;

package Ada.Float_Text_IO is new Ada.Text_IO.Float_IO (Float);
You can use it directly with any object of floating-point type. For example:

Listing 18: show_float_text_io.adb

```ada
with Ada.Float_Text_IO;

procedure Show_Float_Text_IO is
  X : constant Float := 2.5;
  use Ada.Float_Text_IO;
begin
  Put (X);
end Show_Float_Text_IO;
```

Code block metadata

Project: Courses.Intro_To_Ada.Generics.Show_Float_Text_IO
MD5: 7cc9b547ef301a2071e9fb65caa4631b

Runtime output

2.50000E+00

Instantiating generic I/O packages can be useful for derived types. For example, let's create a new type `Price` that must be displayed with two decimal digits after the point, and no exponent.

Listing 19: show_float_io_inst.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Float_IO_INST is
  type Price is digits 3;
  package Price_IO is new Ada.Text_IO.Float_IO (Price);
  P : Price;
begin
  -- Set to zero => don't display exponent
  Price_IO.Default_Exp := 0;
  P := 2.5;
  Price_IO.Put (P);
  New_Line;
  P := 5.75;
  Price_IO.Put (P);
  New_Line;
end Show_Float_IO_INST;
```

Code block metadata

Project: Courses.Intro_To_Ada.Generics.Show_Float_IO_INST
MD5: 583c761421d7fdb812dd2a183b676bae

Runtime output

2.50
5.75

By adjusting `Default_Exp` from the `Price_IO` instance to remove the exponent, we can
control how variables of Price type are displayed. Just as a side note, we could also have written:

```
-- [...]  

  type Price is new Float;
  
  package Price_IO is new
      Ada.Text_IO.Float_IO (Price);

begin
  Price_IO.Default_Aft := 2;
  Price_IO.Default_Exp := 0;
```

In this case, we’re adjusting Default_Aft, too, to get two decimal digits after the point when calling Put.

In addition to the generic Float_IO package, the following generic packages are available from Ada.Text_IO:

• Enumeration_IO for enumeration types;
• Integer_IO for integer types;
• Modular_IO for modular types;
• Fixed_IO for fixed-point types;
• Decimal_IO for decimal types.

In fact, we could rewrite the example above using decimal types:

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Decimal_IO_Inst is

  type Price is delta 10.0 ** (-2) digits 12;

  package Price_IO is new
      Ada.Text_IO.Decimal_IO (Price);

  P : Price;

begin
  Price_IO.Default_Exp := 0;

  P := 2.5;
  Price_IO.Put (P);
  New_Line;

  P := 5.75;
  Price_IO.Put (P);
  New_Line;
end Show_Decimal_IO_Inst;
```

13.8. Example: I/O instances
13.9 Example: ADTs

An important application of generics is to model abstract data types (ADTs). In fact, Ada includes a library with numerous ADTs using generics: Ada.Containers (described in the containers section (page 199)).

A typical example of an ADT is a stack:

Listing 21: stacks.ads

generic
Max : Positive;
type T is private;
package Stacks is

type Stack is limited private;
    Stack_Underflow, Stack_Overflow : exception;
    function Is_Empty (S : Stack) return Boolean;
    function Pop (S : in out Stack) return T;
    procedure Push (S : in out Stack;
                    V : T);

private

    type Stack_Array is
        array (Natural range <>) of T;
    Min : constant := 1;

    type Stack is record
        Container : Stack_Array (Min .. Max);
        Top : Natural := Min - 1;
    end record;
end Stacks;

Listing 22: stacks.adb

package body Stacks is

    function Is_Empty (S : Stack) return Boolean is
        (S.Top < S.Container'First);
    end Is_Empty;

    function Is_Full (S : Stack) return Boolean is
        (S.Top >= S.Container'Last);
    end Is_Full;

    function Pop (S : in out Stack) return T is
        begin
            if Is_Empty (S) then
                raise Stack_Underflow;
            else
                return X : T do
                    X := S.Container (S.Top);
                    S.Top := S.Top - 1;
                end return;
            end if;
        end Pop;
(continues on next page)
procedure Push (S : in out Stack;  
    V : T) is  
begin  
    if Is_Full (S) then  
        raise Stack_Overflow;  
    else  
        S.Top := S.Top + 1;  
        S.Container (S.Top) := V;  
    end if;  
end Push;  

end Stacks;  

Listing 23: show_stack.adb  
with Ada.Text_IO; use Ada.Text_IO;  
with Stacks;  
procedure Show_Stack is  
package Integer_Stacks is new  
Stacks (Max => 10,  
        T => Integer);  
use Integer_Stacks;  
Values : Integer_Stacks.Stack;  
begin  
    Push (Values, 10);  
    Push (Values, 20);  
    Put_Line ("Last value was "  
              & Integer'Image (Pop (Values)));  
end Show_Stack;  

Code block metadata  
MD5: ee112d395552c1a02d211b9e5425dc71  

Runtime output  
Last value was  20  

In this example, we first create a generic stack package (Stacks) and then instantiate it to create a stack of up to 10 integer values.  

13.10 Example: Swap  
Let's look at a simple procedure that swaps variables of type Color:  

Listing 24: colors.ads  
package Colors is  
    type Color is (Black, Red, Green,  
                   Blue, White);  
(continues on next page)
package body Colors is

   procedure Swap_Colors (X, Y : in out Color) is
      Tmp : constant Color := X;
   begin
      X := Y;
      Y := Tmp;
   end Swap_Colors;

end Colors;

Listing 25: colors.adb

with Ada.Text_IO; use Ada.Text_IO;
with Colors; use Colors;

procedure Test_Non_Generic_Swap_Colors is
   A, B, C : Color;
begin
   A := Blue;
   B := White;
   C := Red;
   Put_Line ("Value of A is ",
              & Color'Image (A));
   Put_Line ("Value of B is ",
              & Color'Image (B));
   Put_Line ("Value of C is ",
              & Color'Image (C));
   New_Line;
   Put_Line ("Swapping A and C...");
   New_Line;
   Swap_Colors (A, C);
   Put_Line ("Value of A is ",
              & Color'Image (A));
   Put_Line ("Value of B is ",
              & Color'Image (B));
   Put_Line ("Value of C is ",
              & Color'Image (C));
end Test_Non_Generic_Swap_Colors;

Listing 26: test_non_generic_swap_colors.adb

Code block metadata

Project: Courses.Intro_To_Ada.Generics.Test_Non_Generic_Swap_Colors
MD5: 4d1cf826a1676c3750a8aabd484ac71f

Runtime output

Value of A is BLUE
Value of B is WHITE
Value of C is RED
Swapping A and C...
In this example, Swap_Colors can only be used for the Color type. However, this algorithm can theoretically be used for any type, whether an enumeration type or a complex record type with many elements. The algorithm itself is the same: it's only the type that differs. If, for example, we want to swap variables of Integer type, we don't want to duplicate the implementation. Therefore, such an algorithm is a perfect candidate for abstraction using generics.

In the example below, we create a generic version of Swap_Colors and name it Generic_Swap. This generic version can operate on any type due to the declaration of formal type T.

Listing 27: generic_swap.ads

```ada
generic
  type T is private;
procedure Generic_Swap (X, Y : in out T);
```

Listing 28: generic_swap.adb

```ada
procedure Generic_Swap (X, Y : in out T) is
  Tmp : constant T := X;
begn
  X := Y;
  Y := Tmp;
end Generic_Swap;
```

Listing 29: colors.ads

```ada
with Generic_Swap;
package Colors is
  type Color is (Black, Red, Green, Blue, White);
  procedure Swap_Colors is new
    Generic_Swap (T => Color);
end Colors;
```

Listing 30: test_swap_colors.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Colors; use Colors;
procedure Test_Swap_Colors is
  A, B, C : Color;
begn
  A := Blue;
  B := White;
  C := Red;
  Put_Line ("Value of A is ",
            & Color'Image (A));
  Put_Line ("Value of B is 
```
As we can see in the example, we can create the same Swap_Colors procedure as we had in the non-generic version of the algorithm by declaring it as an instance of the generic Generic_Swap procedure. We specify that the generic T type will be mapped to the Color type by passing it as an argument to the Generic_Swap instantiation.

13.11 Example: Reversing

The previous example, with an algorithm to swap two values, is one of the simplest examples of using generics. Next we study an algorithm for reversing elements of an array. First, let's start with a non-generic version of the algorithm, one that works specifically for the Color type:

```
package Colors is
  type Color is (Black, Red, Green, Blue, White);
  type Color_Array is array (Integer range <>) of Color;
  procedure Reverse_It (X : in out Color_Array);
end Colors;
```
Listing 32: colors.adb

```ada
package body Colors is

   procedure Reverse_It (X : in out Color_Array)
   is
      begin
         for I in X'First .. (X'Last + X'First) / 2 loop
            declare
               Tmp : Color;  
               X_Left : Color renames X (I);  
               X_Right : Color renames X (X'Last + X'First - I);
            begin
               Tmp := X_Left;  
               X_Left := X_Right;  
               X_Right := Tmp;
            end;
         end loop;
   end Reverse_It;

end Colors;
```

Listing 33: test_non_generic_reverse_colors.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Colors; use Colors;

procedure Test_Non_Generic.Reverse_Colors is
   My_Colors : Color_Array (1 .. 5) :=
               (Black, Red, Green, Blue, White);
   begin
      for C of My_Colors loop
         Put_Line ("My_Color: " & Color'Image (C));
      end loop;
      New_Line;
      Put_Line ("Reversing My_Color...");
      Reverse_It (My_Colors);
      for C of My_Colors loop
         Put_Line ("My_Color: " & Color'Image (C));
      end loop;
   end Test_Non_Generic.Reverse_Colors;
```

**Code block metadata**

MD5: 9b3a489d0bc0ecd79de6ba99fd7cd44f

**Runtime output**

13.11. Example: Reversing
My_Color: BLACK
My_Color: RED
My_Color: GREEN
My_Color: BLUE
My_Color: WHITE

Reversing My_Color...

My_Color: WHITE
My_Color: BLUE
My_Color: GREEN
My_Color: RED
My_Color: BLACK

The procedure Reverse_It takes an array of colors, starts by swapping the first and last elements of the array, and continues doing that with successive elements until it reaches the middle of array. At that point, the entire array has been reversed, as we see from the output of the test program.

To abstract this procedure, we declare formal types for three components of the algorithm:

- the elements of the array (Color type in the example)
- the range used for the array (Integer type in the example)
- the actual array type (Color_Array type in the example)

This is a generic version of the algorithm:

Listing 34: generic_reverse.ads

```
generic
    type T is private;
    type Index is range <>;
    type Array_T is
        array (Index range <>) of T;

procedure Generic_Reverse (X : in out Array_T);
```

Listing 35: generic_reverse.adb

```
procedure Generic_Reverse (X : in out Array_T) is
begin
for I in X'First .. (X'Last + X'First) / 2 loop
    declare
        Tmp : T;
        X_Left : T renames X (I);
        X_Right : T renames X (X'Last + X'First - I);
    begin
        Tmp := X_Left;
        X_Left := X_Right;
        X_Right := Tmp;
    end;
end loop;
end Generic_Reverse;
```

Listing 36: colors.ads

```
with Generic_Reverse;

package Colors is
```

(continues on next page)
type Color is (Black, Red, Green, Blue, White);

type Color_Array is array (Integer range <>) of Color;

procedure Reverse_It is new
  Generic_Reverse (T => Color,
                  Index => Integer,
                  Array_T => Color_Array);

end Colors;

Listing 37: test_reverse_colors.adb

with Ada.Text_IO; use Ada.Text_IO;
with Colors; use Colors;

procedure Test_Reverse_Colors is
  My_Colors : Color_Array (1..5) :=
    (Black, Red, Green, Blue, White);

begin
  for C of My_Colors loop
    Put_Line ("My_Color: ",
              & Color'Image (C));
  end loop;

  New_Line;
  Put_Line ("Reversing My_Color...");
  New_Line;
  Reverse_It (My_Colors);

  for C of My_Colors loop
    Put_Line ("My_Color: ",
              & Color'Image (C));
  end loop;

end Test_Reverse_Colors;

Code block metadata

MD5: 9ef175c517d7574b4b65b24ba0027f1f

Runtime output

My_Color: BLACK
My_Color: RED
My_Color: GREEN
My_Color: BLUE
My_Color: WHITE

Reversing My_Color...

My_Color: WHITE
My_Color: BLUE
My_Color: GREEN
My_Color: RED

(continues on next page)
As mentioned above, we're abstracting three components of the algorithm:

- the T type abstracts the elements of the array
- the Index type abstracts the range used for the array
- the Array_T type abstracts the array type and uses the formal declarations of the T and Index types.

### 13.12 Example: Test application

In the previous example we've focused only on abstracting the reversing algorithm itself. However, we could have decided to also abstract our small test application. This could be useful if we, for example, decide to test other procedures that change elements of an array.

In order to do this, we again have to choose the elements to abstract. We therefore declare the following formal parameters:

- S: the string containing the array name
- a function Image that converts an element of type T to a string
- a procedure Test that performs some operation on the array

Note that Image and Test are examples of formal subprograms and S is an example of a formal object.

Here is a version of the test application making use of the generic Perform_Test procedure:

**Listing 38: generic_reverse.ads**

```ada
generic
  type T is private;
  type Index is range <>;
  type Array_T is
    array (Index range <>) of T;
procedure Generic_Reverse (X : in out Array_T);
```

**Listing 39: generic_reverse.adb**

```ada
procedure Generic_Reverse (X : in out Array_T) is begin
  for I in X'First .. (X'Last + X'First) / 2 loop
    declare
      Tmp : T;
      X_Left : T renames X (I);
      X_Right : T renames X (X'Last + X'First - I);
    begin
      Tmp := X_Left;
      X_Left := X_Right;
      X_Right := Tmp;
    end;
  end loop;
end Generic_Reverse;
```
This section introduces the Ada programming language. A few examples are provided to illustrate its usage.

### Listing 40: perform_test.ads

```ada
generic
  type T is private;
  type Index is range <>;
  type Array_T is
    array (Index range <=) of T;
  S : String;
with function Image (E : T)
  return String is <>;
with procedure Test (X : in out Array_T);
procedure Perform_Test (X : in out Array_T);
```

### Listing 41: perform_test.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Perform_Test (X : in out Array_T) is
begin
  for C of X loop
    Put_Line (S & ": " & Image (C));
  end loop;

  New_Line;
  Put_Line ("Testing " & S & "..."toggleClass);
  New_Line;
  Test (X);

  for C of X loop
    Put_Line (S & ": " & Image (C));
  end loop;
end Perform_Test;
```

### Listing 42: colors.ads

```ada
with Generic.Reverse;

package Colors is
  type Color is (Black, Red, Green, Blue, White);
  type Color_Array is
    array (Integer range <=) of Color;
  procedure Reverse_It is new
    Generic.Reverse (T => Color,
                 Index => Integer,
                 Array_T => Color_Array);
end Colors;
```

### Listing 43: test_reverse_colors.adb

```ada
with Colors; use Colors;
with Perform_Test;

procedure Test.Reverse.Colors is
  procedure Perform.Test.Reverse_It is new
    procedure Perform_Test.Reverse_It (X : in out Array_T)
```

(continues on next page)
In this example, we create the procedure `Perform_Test Reverse_It` as an instance of the generic procedure `Perform_Test`. Note that:

- For the formal `Image` function, we use the `Image` attribute of the `Color` type.
- For the formal `Test` procedure, we reference the `Reverse_Array` procedure from the package.
Ada uses exceptions for error handling. Unlike many other languages, Ada speaks about *raising*, not *throwing*, an exception and *handling*, not *catching*, an exception.

### 14.1 Exception declaration

Ada exceptions are not types, but instead objects, which may be peculiar to you if you're used to the way Java or Python support exceptions. Here's how you declare an exception:

Listing 1: exceptions.ads

```ada
package Exceptions is
  My_Except : exception;
  -- Like an object. *NOT* a type!
end Exceptions;
```

**Code block metadata**

*Project: Courses.Intro_To_Ada.Exceptions.Show_Exception*  
*MD5: 6201faeca9b029c790023856d2c8c419*

Even though they're objects, you're going to use each declared exception object as a "kind" or "family" of exceptions. Ada does not require that a subprogram declare every exception it can potentially raise.

### 14.2 Raising an exception

To raise an exception of our newly declared exception kind, do the following:

Listing 2: main.adb

```ada
with Exceptions; use Exceptions;

procedure Main is
begin
  raise My_Except;
  -- Execution of current control flow abandoned; an exception of kind
  -- "My_Except" will bubble up until it
  -- is caught.
end Main;
```

**Code block metadata**
14.3 Handling an exception

Next, we address how to handle exceptions that were raised by us or libraries that we call. The neat thing in Ada is that you can add an exception handler to any statement block as follows:

```
-- Block (sequence of statements)
begin
  Open (File, In_File, "input.txt");
exception
  when E : Name_Error =>
  -- ^ Exception to be handled
    Put (^Cannot open input file : ");
    Put_Line (Exception_Message (E));
    raise;
-- Reraise current occurrence
```

(continues on next page)
17 end;  
18 end Open_File;

**Code block metadata**

Project: Courses.Intro_To_Ada.Exceptions.Show_Exception_Handling  
MD5: 4ea1d5da684a6d7d7ee32908810e9c8f

**Runtime output**

Cannot open input file: No such file or directory

raised ADA.IO_EXCEPTIONS.NAME_ERROR: input.txt: No such file or directory

In the example above, we’re using the `Exception_Message` function from the Ada.Exceptions package. This function returns the message associated with the exception as a string.

You don’t need to introduce a block just to handle an exception: you can add it to the statements block of your current subprogram:

**Listing 5: open_file.adb**

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Exceptions; use Ada.Exceptions;

procedure Open_File is  
  File : File_Type;  
begin  
  Open (File, In_File, "input.txt");  
-- Exception block can be added to any block  
exception  
  when Name_Error =>  
    Put ("Cannot open input file");  
end Open_File;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Exceptions.Show_Exception_Message  
MD5: 838e87ae416b3a717901cdc00eb71b40

**Runtime output**

Cannot open input file

---

**Attention**

Exception handlers have an important restriction that you need to be careful about: Exceptions raised in the declarative section are not caught by the handlers of that block. So for example, in the following code, the exception will not be caught.

**Listing 6: be_careful.adb**

```ada
with Ada.Text_IO; use Ada.Text_IO;  
with Ada.Exceptions; use Ada.Exceptions;

procedure Be_Careful is  
  function Dangerous return Integer is  
    begin  
      raise Constraint_Error;  
    end Dangerous;
```

(continues on next page)

---

14.3. Handling an exception
Introduction to Ada

(continued from previous page)

```ada
return 42;
end Dangerous;

begin
declare
  A : Integer := Dangerous;
begin
  Put_Line (Integer'Image (A));
exception
  when Constraint_Error =>
    Put_Line ("error!");
end;
end Be_Careful;
```

Code block metadata

Project: Courses.Intro To Ada.Exceptions.Be_Careful
MD5: 6ea8a214bbaaca09d7444136d069e782

Runtime output

raised CONSTRAINT_ERROR : be_careful.adb:7 explicit raise

This is also the case for the top-level exception block that is part of the current subprogram.

14.4 Predefined exceptions

Ada has a very small number of predefined exceptions:

- **Constraint_Error** is the main one you might see. It's raised:
  - When bounds don't match or, in general, any violation of constraints.
  - In case of overflow
  - In case of null dereferences
  - In case of division by 0

- **Program_Error** might appear, but probably less often. It's raised in more arcane situations, such as for order of elaboration issues and some cases of detectable erroneous execution.

- **Storage_Error** will happen because of memory issues, such as:
  - Not enough memory (allocator)
  - Not enough stack

- **Tasking_Error** will happen with task related errors, such as any error happening during task activation.

You should not reuse predefined exceptions. If you do then, it won't be obvious when one is raised that it is because something went wrong in a built-in language operation.
Tasks and protected objects allow the implementation of concurrency in Ada. The following sections explain these concepts in more detail.

15.1 Tasks

A task can be thought as an application that runs concurrently with the main application. In other programming languages, a task might be called a thread\footnote{https://en.wikipedia.org/wiki/Thread\_(computing)}, and tasking might be called multithreading\footnote{https://en.wikipedia.org/wiki/Thread\_(computing)#Multithreading}.

Tasks may synchronize with the main application but may also process information completely independently from the main application. Here we show how this is accomplished.

15.1.1 Simple task

Tasks are declared using the keyword task. The task implementation is specified in a task body block. For example:

```ada
with Ada.Text_Io; use Ada.Text_Io;

procedure Show_Simple_Task is
  task T;
  task body T is
    begin
      Put_Line ("In task T");
      end T;
    begin
      Put_Line ("In main");
    end Show_Simple_Task;
```

Listing 1: show_simple_task.adb
Introduction to Ada

Here, we're declaring and implementing the task T. As soon as the main application starts, task T starts automatically — it's not necessary to manually start this task. By running the application above, we can see that both calls to Put_Line are performed.

Note that:

- The main application is itself a task (the main or “environment” task).
  - In this example, the subprogram Show_Simple_Task is the main task of the application.
- Task T is a subtask.
  - Each subtask has a master, which represents the program construct in which the subtask is declared. In this case, the main subprogram Show_Simple_Task is T's master.
  - The master construct is executed by some enclosing task, which we will refer to as the "master task" of the subtask.
- The number of tasks is not limited to one: we could include a task T2 in the example above.
  - This task also starts automatically and runs concurrently with both task T and the main task. For example:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Simple_Tasks is
  task T;
  task T2;

  task body T is
    begin
      Put_Line ("In task T");
      end T;

  task body T2 is
    begin
      Put_Line ("In task T2");
      end T2;

begin
  Put_Line ("In main");
end Show_Simple_Tasks;
```

Code block metadata

Project: Courses.Intro_To_Ada.Tasking.Multiple_Simple_Task
MD5: 5e24b797e742bec306ad498f4f40d2b4

Runtime output

In task T
In task T2
In main
15.1.2 Simple synchronization

As we’ve just seen, as soon as the master construct reaches its “begin”, its subtasks also start automatically. The master continues its processing until it has nothing more to do. At that point, however, it will not terminate. Instead, the master waits until its subtasks have finished before it allows itself to complete. In other words, this waiting process provides synchronization between the master task and its subtasks. After this synchronization, the master construct will complete. For example:

Listing 3: show_simple_sync.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Simple_Sync is
  task T;
  task body T is
    begin
      for I in 1 .. 10 loop
        Put_Line ("hello");
      end loop;
    end T;
  begin
    null;
    -- Will wait here until all tasks
    -- have terminated
  end Show_Simple_Sync;
```

The same mechanism is used for other subprograms that contain subtasks: the subprogram execution will wait for its subtasks to finish. So this mechanism is not limited to the main subprogram and also applies to any subprogram called by the main subprogram, directly or indirectly.

Synchronization also occurs if we move the task to a separate package. In the example below, we declare a task T in the package Simple_Sync_Pkg.
Introduction to Ada

Listing 4: simple_sync_pkg.ads

```ada
package Simple_Sync_Pkg is
task T;
end Simple_Sync_Pkg;
```

Code block metadata

Project: Courses.Intro_To_Ada.Tasking.Simple_Sync_Pkg
MD5: 2f9be044d0499420970f150e22935e

This is the corresponding package body:

Listing 5: simple_sync_pkg.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
package body Simple_Sync_Pkg is
task body T is
  begin
    for I in 1 .. 10 loop
      Put_Line ("hello");
    end loop;
  end T;
end Simple_Sync_Pkg;
```

Code block metadata

Project: Courses.Intro_To_Ada.Tasking.Simple_Sync_Pkg
MD5: b668451e4fb10e802f619889bcd743ff

Because the package is `with`ed by the main procedure, the task `T` defined in the package will become a subtask of the main task. For example:

Listing 6: test_simple_sync_pkg.adb

```ada
with Simple_Sync_Pkg;

procedure Test_Simple_Sync_Pkg is
begin
  null;
  -- Will wait here until all tasks
  -- have terminated
  end Test_Simple_Sync_Pkg;
```

Code block metadata

Project: Courses.Intro_To_Ada.Tasking.Simple_Sync_Pkg
MD5: e51565b91767ce198496ef3e9c582ac8

Runtime output

```
hello
hello
hello
hello
hello
hello
hello
hello
hello
hello
```
As soon as the main subprogram returns, the main task synchronizes with any subtasks spawned by packages T from Simple_Sync_Pkg before finally terminating.

### 15.1.3 Delay

We can introduce a delay by using the keyword `delay`. This puts the current task to sleep for the length of time (in seconds) specified in the delay statement. For example:

Listing 7: show_delay.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Delay is

  task T;

  task body T is
    begin
      for I in 1 .. 5 loop
        Put_Line ("hello from task T");
        delay 1.0;
        -- ^ Wait 1.0 seconds
      end loop;
    end T;

  begin
    delay 1.5;
    Put_Line ("hello from main");
  end Show_Delay;

```

Code block metadata

**Project:** Courses.Intro_To_Ada.Tasking.Show_Delay  
**MD5:** 4a6e8039744301a128e8fb2dd27902a5

Runtime output

```
hello from task T
hello from task T
hello from main
hello from task T
hello from task T
```

In this example, we're making the task `T` wait one second after each time it displays the "hello" message. In addition, the main task is waiting 1.5 seconds before displaying its own "hello" message.

### 15.1.4 Synchronization: rendezvous

The only type of synchronization we've seen so far is the one that happens automatically at the end of a master construct with a subtask. You can also define custom synchronization points using the keyword `entry`. An entry can be viewed as a special kind of subprogram, which is called by another task using a similar syntax, as we will see later.

In the task body definition, you define which part of the task will accept the entries by using the keyword `accept`. A task proceeds until it reaches an `accept` statement and then waits for some other task to synchronize with it. Specifically,

- The task with the entry waits at that point (in the `accept` statement), ready to accept a call to the corresponding entry from the master task.
The other task calls the task entry, in a manner similar to a procedure call, to synchronize with the entry. This synchronization between tasks is called a **rendezvous**. Let’s see an example:

### Listing 8: show_rendezvous.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Rendezvous is

  task T is
    entry Start;
  end T;

  task body T is
    begin
      accept Start;
        -- ^ Waiting for somebody
        -- to call the entry
        Put_Line ("In T");
      end T;
  begin
    Put_Line ("In Main");
      -- Calling T's entry:
    T.Start;
  end Show_Rendezvous;
```

**Code block metadata**

- **Project**: Courses.Intro_To_Ada.Tasking.Show_Rendezvous
- **MD5**: 479eea7ad8769c359ad20ac6e3acf66

**Runtime output**

```
In Main
In T
```

In this example, we declare an entry **Start** for task **T**. In the task body, we implement this entry using **accept** **Start**. When task **T** reaches this point, it waits for some other task to call its entry. This synchronization occurs in the **T.Start** statement. After the rendezvous completes, the main task and task **T** again run concurrently until they synchronize one final time when the main subprogram **Show_Rendezvous** finishes.

An entry may be used to perform more than a simple task synchronization: it also may perform multiple statements during the time both tasks are synchronized. We do this with a **do ... end** block. For the previous example, we would simply write **accept** **Start** **do** <statements>; **end**;. We use this kind of block in the next example.
15.1.5 Select loop

There's no limit to the number of times an entry can be accepted. We could even create an infinite loop in the task and accept calls to the same entry over and over again. An infinite loop, however, prevents the subtask from finishing, so it blocks its master task when it reaches the end of its processing. Therefore, a loop containing accept statements in a task body can be used in conjunction with a select ... or terminate statement. In simple terms, this statement allows its master task to automatically terminate the subtask when the master construct reaches its end. For example:

Listing 9: show_rendezvous_loop.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Rendezvous_Loop is

  task T is
    entry Reset;
    entry Increment;
  end T;

  task body T is
    Cnt : Integer := 0;
  begin
    loop
      select
        accept Reset do
          Cnt := 0;
          end Reset;
          Put_Line ("Reset");
        or
          accept Increment do
            Cnt := Cnt + 1;
            end Increment;
            Put_Line ("In T's loop (" & Integer'Image (Cnt) & ")");
          or
            terminate;
        end select;
      end loop;
    end T;
  begin
    Put_Line ("In Main");
    for I in 1 .. 4 loop
      -- Calling T's entry multiple times
      T.Increment;
    end loop;
    T.Reset;
    for I in 1 .. 4 loop
      -- Calling T's entry multiple times
      T.Increment;
    end loop;
  end Show_Rendezvous_Loop;
```

Code block metadata
In this example, the task body implements an infinite loop that accepts calls to the \texttt{Reset} and \texttt{Increment} entry. We make the following observations:

- The \texttt{accept E do ... end} block is used to increment a counter.
  - As long as task \texttt{T} is performing the \texttt{do ... end} block, the main task waits for the block to complete.
- The main task is calling the \texttt{Increment} entry multiple times in the loop from 1 .. 4. It is also calling the \texttt{Reset} entry before the second loop.
  - Because task \texttt{T} contains an infinite loop, it always accepts calls to the \texttt{Reset} and \texttt{Increment} entries.
  - When the master construct of the subtask (the \texttt{Show_Rendezvous_Loop} subprogram) completes, it checks the status of the \texttt{T} task. Even though task \texttt{T} could accept new calls to the \texttt{Reset} or \texttt{Increment} entries, the master construct is allowed to terminate task \texttt{T} due to the \texttt{or terminate} part of the \texttt{select} statement.

### 15.1.6 Cycling tasks

In a previous example, we saw how to delay a task a specified time by using the \texttt{delay} keyword. However, using delay statements in a loop is not enough to guarantee regular intervals between those delay statements. For example, we may have a call to a computationally intensive procedure between executions of successive delay statements:

\begin{verbatim}
while True loop
  delay 1.0;
  -- ^ Wait 1.0 seconds
  Computational_Intensive_App;
end loop;
\end{verbatim}

In this case, we can’t guarantee that exactly 10 seconds have elapsed after 10 calls to the delay statement because a time drift may be introduced by the \texttt{Computational_Intensive_App} procedure. In many cases, this time drift is not relevant, so using the \texttt{delay} keyword is good enough.

However, there are situations where a time drift isn’t acceptable. In those cases, we need to use the \texttt{delay until} statement, which accepts a precise time for the end of the delay, allowing us to define a regular interval. This is useful, for example, in real-time applications.

We will soon see an example of how this time drift may be introduced and how the \texttt{delay until} statement circumvents the problem. But before we do that, we look at a package containing a procedure allowing us to measure the elapsed time (\texttt{Show_Elapsed_Time}) and a dummy \texttt{Computational_Intensive_App} procedure which is simulated by using a simple delay. This is the complete package:
with Ada.Real_Time; use Ada.Real_Time;

package Delay_Aux_Pkg is

   function Get_Start_Time return Time with Inline;

   procedure Show_Elapsed_Time with Inline;

   procedure Computational_Intensive_App;

private

   Start_Time : Time := Clock;

   function Get_Start_Time return Time is
      (Start_Time);

end Delay_Aux_Pkg;

with Ada.Text_IO; use Ada.Text_IO;

package body Delay_Aux_Pkg is

   procedure Show_Elapsed_Time is
      Now_Time : Time;
      Elapsed_Time : Time_Span;
      begin
         Now_Time := Clock;
         Elapsed_Time := Now_Time - Start_Time;
         Put_Line ("Elapsed time " & Duration'Image
                     (To_Duration (Elapsed_Time)) & " seconds");
      end Show_Elapsed_Time;

   procedure Computational_Intensive_App is
      begin
         delay 0.5;
      end Computational_Intensive_App;

end Delay_Aux_Pkg;

Using this auxiliary package, we’re now ready to write our time-drifting application:

Listing 12: show_time_task.adb

with Ada.Text_IO; use Ada.Text_IO;
with Ada.Real_Time; use Ada.Real_Time;
with Delay_Aux_Pkg;

procedure Show_Time_Task is
package Aux renames Delay_Aux_Pkg;

task T;

task body T is
  Cnt : Integer := 1;
begin
  for I in 1 .. 5 loop
    delay 1.0;
    Aux.Show_Elapsed_Time;
    Aux.Computational_Intensive_App;
    Put_Line ("Cycle # " & Integer'Image (Cnt));
    Cnt := Cnt + 1;
  end loop;
  Put_Line ("Finished time-drifting loop");
end T;

begin
  null;
end Show_Time_Task;

Code block metadata
Project: Courses.Intro_To_Ada.Tasking.Show_Time
MD5: fe17c902fc127c0132677ea4005ff3f1

Runtime output
Elapsed time 1.000528681 seconds
Cycle # 1
Elapsed time 2.501496814 seconds
Cycle # 2
Elapsed time 4.002310614 seconds
Cycle # 3
Elapsed time 5.502655881 seconds
Cycle # 4
Elapsed time 7.012303672 seconds
Cycle # 5
Finished time-drifting loop

We can see by running the application that we already have a time difference of about four seconds after three iterations of the loop due to the drift introduced by Computational_Intensive_App. Using the *delay until* statement, however, we're able to avoid this time drift and have a regular interval of exactly one second:

Listing 13: show_time_task.adb

```
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Real_Time; use Ada.Real_Time;
with Delay_Aux_Pkg;

procedure Show_Time_Task is
  package Aux renames Delay_Aux_Pkg;
  task T;
  task body T is
```

(continues on next page)
Cycle : constant Time_Span :=
  Milliseconds (1000);
Next : Time := Aux.Get_Start_Time
  + Cycle;

Cnt : Integer := 1;
begin
  for I in 1 .. 5 loop
    delay until Next;
    Aux.Show_Elapsed_Time;
    Aux.Computational_Intensive_App;
    -- Calculate next execution time
    -- using a cycle of one second
    Next := Next + Cycle;
    Put_Line ("Cycle # "
      & Integer'Image (Cnt));
    Cnt := Cnt + 1;
  end loop;
  Put_Line ("Finished cycling");
end T;

begin
  null;
end Show_Time_Task;

Code block metadata

Project: Courses.Intro_To_Ada.Tasking.Show_Time
MD5: 1456c0fee6def8b370d994c0ab75a15

Runtime output

Elapsed time 1.000196297 seconds
Cycle # 1
Elapsed time 2.000175312 seconds
Cycle # 2
Elapsed time 3.000143616 seconds
Cycle # 3
Elapsed time 4.000112505 seconds
Cycle # 4
Elapsed time 5.000108386 seconds
Cycle # 5
Finished cycling

Now, as we can see by running the application, the delay until statement ensures that the Computational_Intensive_App doesn't disturb the regular interval of one second between iterations.
### 15.2 Protected objects

When multiple tasks are accessing shared data, corruption of that data may occur. For example, data may be inconsistent if one task overwrites parts of the information that's being read by another task at the same time. In order to avoid these kinds of problems and ensure information is accessed in a coordinated way, we use **protected objects**.

Protected objects encapsulate data and provide access to that data by means of *protected operations*, which may be subprograms or protected entries. Using protected objects ensures that data is not corrupted by race conditions or other concurrent access.

**Important**

Objects can be protected from concurrent access using Ada tasks. In fact, this was the only way of protecting objects from concurrent access in Ada 83 (the first version of the Ada language). However, the use of protected objects is much simpler than using similar mechanisms implemented using only tasks. Therefore, you should use protected objects when your main goal is only to protect data.

#### 15.2.1 Simple object

You declare a protected object with the *protected* keyword. The syntax is similar to that used for packages: you can declare operations (e.g., procedures and functions) in the public part and data in the private part. The corresponding implementation of the operations is included in the *protected body* of the object. For example:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Protected_Objects is

protected Obj is
  -- Operations go here (only subprograms)
  procedure Set (V : Integer);
  function Get return Integer;

private
  -- Data goes here
  Local : Integer := 0;
end Obj;

protected body Obj is
  -- procedures can modify the data
  procedure Set (V : Integer) is
    begin
      Local := V;
    end Set;

  -- functions cannot modify the data
  function Get return Integer is
    begin
      return Local;
    end Get;
end Obj;

begin
  Obj.Set (5);
(continues on next page)
```
In this example, we define two operations for Obj: Set and Get. The implementation of these operations is in the Obj body. The syntax used for writing these operations is the same as that for normal procedures and functions. The implementation of protected objects is straightforward — we simply access and update Local in these subprograms. To call these operations in the main application, we use prefixed notation, e.g., Obj.Get.

15.2.2 Entries

In addition to protected procedures and functions, you can also define protected entry points. Do this using the entry keyword. Protected entry points allow you to define barriers using the when keyword. Barriers are conditions that must be fulfilled before the entry can start performing its actual processing — we speak of releasing the barrier when the condition is fulfilled.

The previous example used procedures and functions to define operations on the protected objects. However, doing so permits reading protected information (via Obj.Get) before it's set (via Obj.Set). To allow that to be a defined operation, we specified a default value (0). Instead, by rewriting Obj.Get using an entry instead of a function, we implement a barrier, ensuring no task can read the information before it's been set.

The following example implements the barrier for the Obj.Get operation. It also contains two concurrent subprograms (main task and task T) that try to access the protected object.

Listing 15: show_protected_objects_entries.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Protected_Objects_Entries is

  protected Obj is
    procedure Set (V : Integer);
    entry Get (V : out Integer);
  private
    Local : Integer;
    Is_Set : Boolean := False;
  end Obj;

  protected body Obj is
    procedure Set (V : Integer) is
      begin
        Local := V;
        Is_Set := True;
      end Set;

    entry Get (V : out Integer)
      when Is_Set is
```
-- Entry is blocked until the
-- condition is true. The barrier
-- is evaluated at call of entries
-- and at exits of procedures and
-- entries. The calling task sleeps
-- until the barrier is released.
begin
  V := Local;
  Is_Set := False;
end Get;
end Obj;
N : Integer := 0;
task T;
task body T is
begin
  Put_Line
  ("Task T will delay for 4 seconds...");
delay 4.0;
  Put_Line
  ("Task T will set Obj...");
  Obj.Set (5);
  Put_Line
  ("Task T has just set Obj...");
end T;
begin
  Put_Line
  ("Main application will get Obj...");
  Obj.Get (N);
  Put_Line
  ("Main application has retrieved Obj...");
  Put_Line
  ("Number is: " & Integer'Image (N));
end Show_Protected_Objects_Entries;

As we see by running it, the main application waits until the protected object is set (by the
call to Obj.Set in task T) before it reads the information (via Obj.Get). Because a 4-second
delay has been added in task T, the main application is also delayed by 4 seconds. Only
after this delay does task T set the object and release the barrier in Obj.Get so that the
main application can then resume processing (after the information is retrieved from the
protected object).
15.3 Task and protected types

In the previous examples, we defined single tasks and protected objects. We can, however, generalize tasks and protected objects using type definitions. This allows us, for example, to create multiple tasks based on just a single task type.

15.3.1 Task types

A task type is a generalization of a task. The declaration is similar to simple tasks: you replace `task` with `task type`. The difference between simple tasks and task types is that task types don't create actual tasks that automatically start. Instead, a task object declaration is needed. This is exactly the way normal variables and types work: objects are only created by variable definitions, not type definitions.

To illustrate this, we repeat our first example:

Listing 16: show_simple_task.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Simple_Task is
  task T;
  task body T is
    begin
      Put_Line ("In task T");
      begin
        Put_Line ("In main");
      end Show_Simple_Task;
  begin
    Put_Line ("In main");
  end Show_Simple_Task;
```

Code block metadata

Project: Courses.Intro_To_Ada.Tasking.Show_Simple_Task
MD5: b17d9b35b4b2b53bc59776749e1be219

Runtime output

In task T
In main

We now rewrite it by replacing `task` `T` with `task type` `TT`. We declare a task (A_Task) based on the task type `TT` after its definition:

Listing 17: show_simple_task_type.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Simple_Task_Type is
  task type TT;
  task body TT is
    begin
      Put_Line ("In task type TT");
      end TT;
    begin
      Put_Line ("In main");
    end Show_Simple_Task_Type;
  A_Task : TT;
  begin
    Put_Line ("In main");
  end Show_Simple_Task_Type;
```
We can extend this example and create an array of tasks. Since we're using the same syntax as for variable declarations, we use a similar syntax for task types: `array (<>) of Task_Type`. Also, we can pass information to the individual tasks by defining a `Start` entry. Here’s the updated example:

```
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Task_Type_Array is
  task type TT is
    entry Start (N : Integer);
  end TT;

  task body TT is
    Task_N : Integer;
    begin
      accept Start (N : Integer) do
        Task_N := N;
      end Start;
      Put_Line ("In task T: ",& Integer'Image (Task_N));
      end TT;

  My_Tasks : array (1 .. 5) of TT;
  begin
    Put_Line ("In main");
    for I in My_Tasks'Range loop
      My_Tasks (I).Start (I);
    end loop;
    end Show_Task_Type_Array;
```

In this example, we're declaring five tasks in the array `My_Tasks`. We pass the array index to the individual tasks in the entry point (`Start`). After the synchronization between the individual subtasks and the main task, each subtask calls `Put_Line` concurrently.
15.3.2 Protected types

A protected type is a generalization of a protected object. The declaration is similar to that for protected objects: you replace `protected` with `protected type`. Like task types, protected types require an object declaration to create actual objects. Again, this is similar to variable declarations and allows for creating arrays (or other composite objects) of protected objects.

We can reuse a previous example and rewrite it to use a protected type:

Listing 19: show_protected_object_type.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Protected_Object_Type is

  protected type P_Obj_Type is
    procedure Set (V : Integer);
    function Get return Integer;
  private
    Local : Integer := 0;
  end P_Obj_Type;

  protected body P_Obj_Type is
    procedure Set (V : Integer) is
      begin
        Local := V;
      end Set;

    function Get return Integer is
      begin
        return Local;
      end Get;
  end P_Obj_Type;

  Obj : P_Obj_Type;

begin
  Obj.Set (5);
  Put_Line ("Number is: ", Integer'Image (Obj.Get));
end Show_Protected_Object_Type;
```

In this example, instead of directly defining the protected object Obj, we first define a protected type `P_Obj_Type` and then declare Obj as an object of that protected type. Note that the main application hasn't changed: we still use `Obj.Set` and `Obj.Get` to access the protected object, just like in the original example.
Contracts are used in programming to codify expectations. Parameter modes of a subprogram can be viewed as a simple form of contracts. When the specification of subprogram \( Op \) declares a parameter using \texttt{in} mode, the caller of \( Op \) knows that the \texttt{in} argument won't be changed by \( Op \). In other words, the caller expects that \( Op \) doesn't modify the argument it's providing, but just reads the information stored in the argument. Constraints and subtypes are other examples of contracts. In general, these specifications improve the consistency of the application.

Design-by-contract programming refers to techniques that include pre- and postconditions, subtype predicates, and type invariants. We study those topics in this chapter.

### 16.1 Pre- and postconditions

Pre- and postconditions provide expectations regarding input and output parameters of subprograms and return value of functions. If we say that certain requirements must be met before calling a subprogram \( Op \), those are preconditions. Similarly, if certain requirements must be met after a call to the subprogram \( Op \), those are postconditions. We can think of preconditions and postconditions as promises between the subprogram caller and the callee: a precondition is a promise from the caller to the callee, and a postcondition is a promise in the other direction.

Pre- and postconditions are specified using an aspect clause in the subprogram declaration. A \texttt{with Pre \texttt{=>} <condition>} clause specifies a precondition and a \texttt{with Post \texttt{=>} <condition>} clause specifies a postcondition.

The following code shows an example of preconditions:

```ada
procedure Show_Simple_Precondition is

    procedure DB_Entry (Name : String; Age : Natural)
    with Pre => Name'Length > 0
    begin
        -- Missing implementation
        null;
    end DB_Entry;

begin
    DB_Entry ("John", 30);
    -- Precondition will fail!
    DB_Entry ("", 21);

end Show_Simple_Precondition;
```

Listing 1: show_simple_precondition.adb
In this example, we want to prevent the name field in our database from containing an empty string. We implement this requirement by using a precondition requiring that the length of the string used for the Name parameter of the DB_Entry procedure is greater than zero. If the DB_Entry procedure is called with an empty string for the Name parameter, the call will fail because the precondition is not met.

In the GNAT toolchain

GNAT handles pre- and postconditions by generating runtime assertions for them. By default, however, assertions aren't enabled. Therefore, in order to check pre- and postconditions at runtime, you need to enable assertions by using the -gnata switch.

Before we get to our next example, let's briefly discuss quantified expressions, which are quite useful in concisely writing pre- and postconditions. Quantified expressions return a Boolean value indicating whether elements of an array or container match the expected condition. They have the form: (for all I in A'Range => <condition on A(I)>), where A is an array and I is an index. Quantified expressions using for all check whether the condition is true for every element. For example:

(for all I in A'Range => A (I) = 0)

This quantified expression is only true when all elements of the array A have a value of zero.

Another kind of quantified expressions uses for some. The form looks similar: (for some I in A'Range => <condition on A(I)>). However, in this case the qualified expression tests whether the condition is true only on some elements (hence the name) instead of all elements.

We illustrate postconditions using the following example:

Listing 2: show_simple_postcondition.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Simple_Postcondition is

  type Int_8 is range -2 ** 7 .. 2 ** 7 - 1;
  type Int_8_Array is
    array (Integer range <>) of Int_8;

  function Square (A : Int_8) return Int_8 is
    (A * A)
    with Post => (if abs A in 0 | 1
      then Square'Result = abs A
      else Square'Result > A);

  procedure Square (A : in out Int_8_Array)
    with Post => (for all I in A'Range =>
      A (I) = A'Old (I) *
```
We declare a signed 8-bit type `Int_8` and an array of that type (`Int_8_Array`). We want to ensure each element of the array is squared after calling the procedure `Square` for an object of the `Int_8_Array` type. We do this with a postcondition using a `for all` expression. This postcondition also uses the `Old` attribute to refer to the original value of the parameter (before the call).

We also want to ensure that the result of calls to the `Square` function for the `Int_8` type are greater than the input to that call. To do that, we write a postcondition using the `Result` attribute of the function and comparing it to the input value.

We can use both pre- and postconditions in the declaration of a single subprogram. For example:

Listing 3: show_simple_contract.adb

```ada
with Ada.Text_I0; use Ada.Text_I0;
```

16.1. Pre- and postconditions
procedure Show_Simple_Contract is

  type Int_8 is range -2 ** 7 .. 2 ** 7 - 1;

  function Square (A : Int_8) return Int_8 is
    (A * A) with
      Pre  => (Integer'Size >= Int_8'Size * 2
                 and Integer (A) *
                 Integer (A) <=
                 Integer (Int_8'Last)),

      Post  => (if abs A in 0 | 1
              then Square'Result = abs A
              else Square'Result > A);

  V : Int_8;

begin
  V := Square (11);
  Put_Line ("Square of 11 is " & Int_8'Image (V));

  -- Precondition will fail...
  V := Square (12);
  Put_Line ("Square of 12 is " & Int_8'Image (V));

end Show_Simple_Contract;

In this example, we want to ensure that the input value of calls to the Square function for the Int_8 type won't cause overflow in that function. We do this by converting the input value to the Integer type, which is used for the temporary calculation, and check if the result is in the appropriate range for the Int_8 type. We have the same postcondition in this example as in the previous one.

16.2 Predicates

Predicates specify expectations regarding types. They're similar to pre- and postconditions, but apply to types instead of subprograms. Their conditions are checked for each object of a given type, which allows verifying that an object of type T is conformant to the requirements of its type.

There are two kinds of predicates: static and dynamic. In simple terms, static predicates are used to check objects at compile-time, while dynamic predicates are used for checks at run time. Normally, static predicates are used for scalar types and dynamic predicates for the more complex types.

Static and dynamic predicates are specified using the following clauses, respectively:
• with Static_Predicate => <property>
• with Dynamic_Predicate => <property>

Let's use the following example to illustrate dynamic predicates:

Listing 4: show_dynamic_predicate_courses.adb

```
with Ada.Calendar; use Ada.Calendar;
with Ada.Containers.Vectors;
with Ada.Strings.Unbounded;
use Ada.Strings.Unbounded;
procedure Show_Dynamic_PREDicate_Courses is
package Courses is
type Course_Container is private;
type Course is record
  Name : Unbounded_String;
  Start_Date : Time;
  End_Date : Time;
end record
  with Dynamic_Predicate =>
    Course.Start_Date <= Course.End_Date;
  procedure Add (CC : in out Course_Container;
    C : Course);
private
  package Course_Vectors is new
    Ada.Containers.Vectors
      (Index_Type  => Natural,
       Element_Type => Course);
type Course_Container is record
  V : Course_Vectors.Vector;
end record;
end Courses;
package body Courses is
  procedure Add (CC : in out Course_Container;
    C : Course) is
    begin
      CC.V.Append (C);
    end Add;
end Courses;
use Courses;
CC : Course_Container;
begin
  Add (CC,
  Course'("Intro to Photography",
    Start_Date => Time_Of (2018, 5, 1),
    End_Date  => Time_Of (2018, 5, 10)));
```

(continues on next page)
In this example, the package Courses defines a type Course and a type Course_Container, an object of which contains all courses. We want to ensure that the dates of each course are consistent, specifically that the start date is no later than the end date. To enforce this rule, we declare a dynamic predicate for the Course type that performs the check for each object. The predicate uses the type name where a variable of that type would normally be used: this is a reference to the instance of the object being tested.

Note that the example above makes use of unbounded strings and dates. Both types are available in Ada’s standard library. Please refer to the following sections for more information about:

- the unbounded string type (Unbounded_String): Unbounded Strings (page 242) section;
- dates and times: Dates & Times (page 227) section.

Static predicates, as mentioned above, are mostly used for scalar types and checked during compilation. They’re particularly useful for representing non-contiguous elements of an enumeration. A classic example is a list of week days:

```
type Week is (Mon, Tue, Wed, Thu, Fri, Sat, Sun);
```

We can easily create a sub-list of work days in the week by specifying a subtype with a range based on Week. For example:

```
subtype Work_Week is Week range Mon .. Fri;
```

Ranges in Ada can only be specified as contiguous lists: they don’t allow us to pick specific days. However, we may want to create a list containing just the first, middle and last day of the work week. To do that, we use a static predicate:

```
subtype Check_Days is Work_Week
  with Static_Predicate =>
    Check_Days in Mon | Wed | Fri;
```

Let’s look at a complete example:
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Predicates is

   type Week is (Mon, Tue, Wed, Thu,
                 Fri, Sat, Sun);

   subtype Work_Week is Week range Mon .. Fri;

   subtype Test_Days is Work_Week
      with Static_Predicate =>
      Test_Days in Mon | Wed | Fri;

   type Tests_Week is array (Week) of Natural
      with Dynamic_Predicate =>
      (for all I in Tests_Week'Range =>
       (case I is
        when Test_Days =>
          Tests_Week (I) > 0,
        when others =>
          Tests_Week (I) = 0));

   Num_Tests : Tests_Week :=
     (Mon => 3, Tue => 0,
      Wed => 4, Thu => 0,
      Fri => 2, Sat => 0,
      Sun => 0);

   procedure Display_Tests (N : Tests_Week) is
      begin
      for I in Test_Days loop
       Put_Line ("# tests on 
                  & Test_Days'Image (I)
                  & " => "
                  & Integer'Image (N (I)));
      end loop;
      end Display_Tests;

   begin
      Display_Tests (Num_Tests);
      -- Assigning non-conformant values to
      -- individual elements of the Tests_Week
      -- type does not trigger a predicate
      -- check:
      Num_Tests (Tue) := 2;
      -- However, assignments with the "complete"
      -- Tests_Week type trigger a predicate
      -- check. For example:
      --
      -- Num_Tests := (others => 0);
      -- Also, calling any subprogram with
      -- parameters of Tests_Week type
      -- triggers a predicate check. Therefore,
      -- the following line will fail:
      Display_Tests (Num_Tests);
   end Show_Predicates;
Here we have an application that wants to perform tests only on three days of the work week. These days are specified in the Test_Days subtype. We want to track the number of tests that occur each day. We declare the type Tests_Week as an array, an object of which will contain the number of tests done each day. According to our requirements, these tests should happen only in the aforementioned three days; on other days, no tests should be performed. This requirement is implemented with a dynamic predicate of the type Tests_Week. Finally, the actual information about these tests is stored in the array Num_Tests, which is an instance of the Tests_Week type.

The dynamic predicate of the Tests_Week type is verified during the initialization of Num_Tests. If we have a non-conformant value there, the check will fail. However, as we can see in our example, individual assignments to elements of the array do not trigger a check. We can't check for consistency at this point because the initialization of the a complex data structure (such as arrays or records) may not be performed with a single assignment. However, as soon as the object is passed as an argument to a subprogram, the dynamic predicate is checked because the subprogram requires the object to be consistent. This happens in the last call to Display_Tests in our example. Here, the predicate check fails because the previous assignment has a non-conformant value.

### 16.3 Type invariants

Type invariants are another way of specifying expectations regarding types. While predicates are used for non-private types, type invariants are used exclusively to define expectations about private types. If a type T from a package P has a type invariant, the results of operations on objects of type T are always consistent with that invariant.

Type invariants are specified with a `with Type.Invariant => <property>` clause. Like predicates, the `property` defines a condition that allows us to check if an object of type T is conformant to its requirements. In this sense, type invariants can be viewed as a sort of predicate for private types. However, there are some differences in terms of checks. The following table summarizes the differences:

<table>
<thead>
<tr>
<th>Element</th>
<th>Subprogram parameter checks</th>
<th>Assignment checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Predicates</td>
<td>On all <code>in</code> and <code>out</code> parameters</td>
<td>On assignments and explicit initializations</td>
</tr>
<tr>
<td>Type invariants</td>
<td>On <code>out</code> parameters returned from subprograms declared in the same public scope</td>
<td>On all initializations</td>
</tr>
</tbody>
</table>

We could rewrite our previous example and replace dynamic predicates by type invariants. It would look like this:
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Calendar; use Ada.Calendar;
with Ada.Containers.Vectors;
with Ada.Strings.Unbounded;
use Ada.Strings.Unbounded;

procedure Show_Type_Invariant is

package Courses is
  type Course is private
    with Type_Invariant => Check (Course);
  type Course_Container is private;
  procedure Add (CC : in out Course_Container; C : Course);
  function Init (Name : String; Start_Date, End_Date : Time) return Course;
  function Check (C : Course) return Boolean;

private
  type Course is record
    Name : Unbounded_String;
    Start_Date : Time;
    End_Date : Time;
  end record;

  function Check (C : Course) return Boolean is
    C.Start_Date <= C.End_Date;

package Course_Vectors is new Ada.Containers.Vectors
  (Index_Type => Natural,
   Element_Type => Course);

  type Course_Container is record
    V : Course_Vectors.Vector;
  end record;
end Courses;

package body Courses is
  procedure Add (CC : in out Course_Container; C : Course) is
    begin
      CC.V.Append (C);
    end Add;

  function Init (Name : String; Start_Date, End_Date : Time) return Course is

(continues on next page)
begin
  return
    Course'(Name =>
        To_Unbounded_String (Name),
        Start_Date => Start_Date,
        End_Date => End_Date);
end Init;
end Courses;

use Courses;

CC : Course_Container;

begin
  Add (CC,
    Init (Name =>
        "Intro to Photography",
        Start_Date =>
            Time_Of (2018, 5, 1),
        End_Date =>
            Time_Of (2018, 5, 10));

-- This should trigger an error in the
-- type-invariant check
  Add (CC,
    Init (Name =>
        "Intro to Video Recording",
        Start_Date =>
            Time_Of (2019, 5, 1),
        End_Date =>
            Time_Of (2018, 5, 10));
end Show_Type_Invariant;

The major difference is that the Course type was a visible (public) type of the Courses package in the previous example, but in this example is a private type.
Ada allows us to interface with code in many languages, including C and C++. This section discusses how to interface with C.

17.1 Multi-language project

By default, when using gprbuild we only compile Ada source files. To compile C files as well, we need to modify the project file used by gprbuild. We use the Languages entry, as in the following example:

```ada
project Multilang is
  for Languages use ("ada", "c");
  for Source_Dirs use ("src");
  for Main use ("main.adb");
  for Object_Dir use "obj";
end Multilang;
```

17.2 Type convention

To interface with data types declared in a C application, you specify the Convention aspect on the corresponding Ada type declaration. In the following example, we interface with the C(Enum enumeration declared in a C source file:

```ada
procedure Show_C_Enum is
  type C(Enum is (A, B, C)
    with Convention => C;
  -- Use C convention for C(Enum
begin
  null;
end Show_C_Enum;
```

Code block metadata

Project: Courses.Intro_To_Ada.Interfacing_With_C.Ada_C_Enum
MD5: a14d7d981fd7d6d86cf3c55f35e19c8
To interface with C's built-in types, we use the Interfaces.C package, which contains most of the type definitions we need. For example:

**Listing 2: show_c_struct.adb**

```ada
with Interfaces.C; use Interfaces.C;

procedure Show_C_Struct is
  type c_struct is record
    a : int;
    b : long;
    c : unsigned;
    d : double;
  end record
  with Convention => C;

begin
  null;
end Show_C_Struct;
```

Here, we're interfacing with a C struct (C_Struct) and using the corresponding data types in C (`int`, `long`, `unsigned` and `double`). This is the declaration in C:

**Listing 3: c_struct.h**

```c
struct c_struct {
  int a;
  long b;
  unsigned c;
  double d;
};
```

### 17.3 Foreign subprograms

#### 17.3.1 Calling C subprograms in Ada

We use a similar approach when interfacing with subprograms written in C. Consider the following declaration in the C header file:

**Listing 4: my_func.h**

```c
int my_func (int a);
```
Here's the corresponding C definition:

```c
#include "my_func.h"

int my_func (int a)
{
    return a * 2;
}
```

### Code block metadata

**Project**: Courses.Intro_To_Ada.Interfacing_With_C.Ada_C_Func  
**MD5**: 284b1639cb393fc14ed196d78429f3ba

We can interface this code in Ada using the Import aspect. For example:

```ada
with Interfaces.C; use Interfaces.C;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_C_Func is

    function my_func (a : int) return int
        with
        import => True,
        Convention => C;
    -- Imports function 'my_func' from C.
    -- You can now call it from Ada.

    V : int;

begin
    V := my_func (2);
    Put_Line ("Result is " & int'Image (V));
end Show_C_Func;
```

### Code block metadata

**Project**: Courses.Intro_To_Ada.Interfacing_With_C.Ada_C_Func  
**MD5**: 6c5d85c1deb6eaa642946eacfc413dfdd2

If you want, you can use a different subprogram name in the Ada code. For example, we could call the C function Get_Value:

```ada
with Interfaces.C; use Interfaces.C;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_C_Func is

    function Get_Value (a : int) return int
        with
        import => True,
        Convention => C,
        External_Name => "my_func";
    -- Imports function 'my_func' from C and
    -- renames it to 'Get_Value'
```

(continues on next page)
14
15
V : int;
begin
  V := Get_Value (2);
  Put_Line ("Result is " & int'Image (V));
end Show_C_Func;

Code block metadata
Project: Courses.Intro_To_Ada.Interfacing_With_C.Ada_C_Func
MD5: 856b4d99dafa6946fb4597f254fd2f97

17.3.2 Calling Ada subprograms in C

You can also call Ada subprograms from C applications. You do this with the Export aspect. For example:

Listing 8: c_api.ads

with Interfaces.C; use Interfaces.C;

package C_API is
  function My_Func (a : int) return int
  with
    Export => True,
    Convention => C,
    External_Name => "my_func";
end C_API;

Code block metadata
Project: Courses.Intro_To_Ada.Interfacing_With_C.Ada_C_Func
MD5: 00aa4ec29fc551e710900e2ee7d96bc9

This is the corresponding body that implements that function:

Listing 9: c_api.adb

package body C_API is
  function My_Func (a : int) return int is
    begin
      return a * 2;
    end My_Func;
end C_API;

Code block metadata
Project: Courses.Intro_To_Ada.Interfacing_With_C.Ada_C_Func
MD5: 2b999ab431bc1ee223a654ad84b8248

On the C side, we do the same as we would if the function were written in C: simply declare it using the extern keyword. For example:
### 17.4 Foreign variables

#### 17.4.1 Using C global variables in Ada

To use global variables from C code, we use the same method as subprograms: we specify the Import and Convention aspects for each variable we want to import.

Let's reuse an example from the previous section. We'll add a global variable (\texttt{func\_cnt}) to count the number of times the function (\texttt{my\_func}) is called:

```
Listing 11: test.h
extern int func\_cnt;
int my\_func (int a);
```

The variable is declared in the C file and incremented in \texttt{my\_func}:

```
Listing 12: test.c
#include "test.h"
int func\_cnt = 0;
int my\_func (int a)
{
    func\_cnt++;
    return a * 2;
}
```

---

**Listing 10: main.c**

```c
#include <stdio.h>

extern int my\_func (int a);

int main (int argc, char **argv) {
    int v = my\_func(2);
    printf("Result is %d\n", v);
    return 0;
}
```

---

**Code block metadata**

MD5: 69301036be9be16ed45895c2a86bc352

---

**17.4 Foreign variables**

**175**
In the Ada application, we just reference the foreign variable:

```ada
with Interfaces.C; use Interfaces.C;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_C_Func is

  function my_func (a : int) return int
  with
    Import => True,
    Convention => C;

  V : int;

  func_cnt : int
  with
    Import => True,
    Convention => C;

  -- We can access the func_cnt variable
  -- from test.c

begin
  V := my_func (1);
  V := my_func (2);
  V := my_func (3);

  Put_Line ("Result is 
    & int'Image (V));

  Put_Line ("Function was called 
    & int'Image (func_cnt)
    & " times");
end Show_C_Func;
```

As we see by running the application, the value of the counter is the number of times `my_func` was called.

We can use the External_Name aspect to give a different name for the variable in the Ada application in the same way we do for subprograms.
17.4.2 Using Ada variables in C

You can also use variables declared in Ada files in C applications. In the same way as we did for subprograms, you do this with the Export aspect.

Let’s reuse a past example and add a counter, as in the previous example, but this time have the counter incremented in Ada code:

Listing 14: c_api.ads

```ada
with Interfaces.C; use Interfaces.C;

package C_API is
  func_cnt : int := 0
  with
    Export => True,
    Convention => C;

  function My_Func (a : int) return int
  with
    Export => True,
    Convention => C,
    External_Name => "my_func";
end C_API;
```

Code block metadata

Project: Courses.Intro_To_Ada.Interfacing_With_C.C_Ada_Vars
MD5: fc118cddd797b669d2c68e57f90f69b2

The variable is then incremented in My_Func:

Listing 15: c_api.adb

```ada
package body C_API is
  function My_Func (a : int) return int is
    begin
      func_cnt := func_cnt + 1;
      return a * 2;
    end My_Func;
end C_API;
```

Code block metadata

Project: Courses.Intro_To_Ada.Interfacing_With_C.C_Ada_Vars
MD5: adff5f3088da8b0dd853f1fb8b1e204f

In the C application, we just need to declare the variable and use it:

Listing 16: main.c

```c
#include <stdio.h>
extern int my_func (int a);
extern int func_cnt;
int main (int argc, char **argv) {
```

(continues on next page)

```ada
int v;

v = my_func(1);

v = my_func(2);

v = my_func(3);

printf("Result is %d\n", v);

printf("Function was called %d times\n", func_cnt);

return 0;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Interfacing_With_C.C_Ada_Vars

MD5: 07fb3fbadb8ed4c0543fbfd7b5ef5c57

Again, by running the application, we see that the value from the counter is the number of times that my_func was called.

### 17.5 Generating bindings

In the examples above, we manually added aspects to our Ada code to correspond to the C source-code we're interfacing with. This is called creating a binding. We can automate this process by using the *Ada spec dump* compiler option: `-fdump-ada-spec`. We illustrate this by revisiting our previous example.

This was our C header file:

```
extern int func_cnt;

int my_func (int a);
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Interfacing_With_C.C_Binds

MD5: 11ba8f7a72ce7058571994870a02b052

To create Ada bindings, we'll call the compiler like this:

```
gcc -c -fdump-ada-spec -C . ./test.h
```

The result is an Ada spec file called `test_h.ads`:

```ada
pragma Ada_2005;
pragma Style_Checks (Off);

with Interfaces.C; use Interfaces.C;

package test_h is
```

(continues on next page)
func_cnt : aliased int; -- ./test.h:3
pragma Import (C, func_cnt, "func_cnt");

function my_func (arg1 : int) return int; -- ./test.h:5
pragma Import (C, my_func, "my_func");
end test_h;

Code block metadata
MD5: 8d18aae72dba3a9ab4f9f3943fab839

Now we simply refer to this test_h package in our Ada application:

Listing 19: show_c_func.adb

with Interfaces.C; use Interfaces.C;
with Ada.Text_IO; use Ada.Text_IO;
with test_h; use test_h;

procedure Show_C_Func is
  V : int;
begin
  V := my_func (1);
  V := my_func (2);
  V := my_func (3);
  Put_Line ("Result is 
    & int'Image (V));
  Put_Line ("Function was called 
    & int'Image (func_cnt)
    & " times");
end Show_C_Func;

Code block metadata
MD5: 8a07aae87b9f36c3fce84b75e8388933

You can specify the name of the parent unit for the bindings you’re creating as the operand to fdump-ada-spec:
gcc -c -fdump-ada-spec -fada-spec-parent=Ext_C_Code -C ./test.h

This creates the file ext_c_code-test_h.ads:

Listing 20: ext_c_code-test_h.ads

package Ext_C_Code.test_h is
  -- automatic generated bindings...
end Ext_C_Code.test_h;

Code block metadata
MD5: 3bd4087e7d1f145a70d2a6dbd8543859ad

17.5. Generating bindings
17.5.1 Adapting bindings

The compiler does the best it can when creating bindings for a C header file. However, sometimes it has to guess about the translation and the generated bindings don't always match our expectations. For example, this can happen when creating bindings for functions that have pointers as arguments. In this case, the compiler may use System\_Address as the type of one or more pointers. Although this approach works fine (as we'll see later), this is usually not how a human would interpret the C header file. The following example illustrates this issue.

Let's start with this C header file:

```c
struct test;
struct test * test_create(void);
void test_destroy(struct test *t);
void test_reset(struct test *t);
void test_set_name(struct test *t, char *name);
void test_set_address(struct test *t, char *address);
void test_display(const struct test *t);
```

And the corresponding C implementation:

```c
#include <stdlib.h>
#include <string.h>
#include <stdio.h>

#include "test.h"

struct test {
    char name[80];
    char address[120];
};

static size_t
strlcpy_stat(char *dst, const char *src, size_t dstsize)
{
    size_t len = strlen(src);
    if (dstsize) {
        size_t bl = (len < dstsize-1 ?
                       len : dstsize-1);
        ((char*)memcpy(dst, src, bl))[bl] = 0;
    }
    return len;
}
```

(continues on next page)
struct test * test_create(void)
{
    return malloc (sizeof (struct test));
}

void test_destroy(struct test *t)
{
    if (t != NULL) {
        free(t);
    }
}

void test_reset(struct test *t)
{
    t->name[0] = '\0';
    t->address[0] = '\0';
}

void test_set_name(struct test *t,
    char *name)
{
    strncpy_stat(t->name, name, sizeof(t->name));
}

void test_set_address(struct test *t,
    char *address)
{
    strncpy_stat(t->address, address, sizeof(t->address));
}

void test_display(const struct test *t)
{
    printf("Name: %s\n", t->name);
    printf("Address: %s\n", t->address);
}

Code block metadata

MD5: 32652eb76ad92212609680d64e5687d3

Next, we'll create our bindings:

```
gcc -c -fdump-ada-spec -C ./test.h
```

This creates the following specification in test_h.ads:

Listing 23: test_h.ads

```
pragma Ada_2005;
pragma Style_Checks (Off);

with Interfaces.C; use Interfaces.C;
with System;
with Interfaces.C.Strings;
```
package test_h is
    -- skipped empty struct test

    function test_create return System.Address; -- ./test.h:5
    pragma Import (C, test_create, "test_create");

    procedure test_destroy (arg1 : System.Address); -- ./test.h:7
    pragma Import (C, test_destroy, "test_destroy");

    procedure test_reset (arg1 : System.Address); -- ./test.h:9
    pragma Import (C, test_reset, "test_reset");

    procedure test_set_name (arg1 : System.Address; arg2 : Interfaces.C.Strings.chars_ptr); -- ./test.h:11
    pragma Import (C, test_set_name, "test_set_name");

    procedure test_set_address (arg1 : System.Address; arg2 : Interfaces.C.Strings.chars_ptr); -- ./test.h:13
    pragma Import (C, test_set_address, "test_set_address");

    procedure test_display (arg1 : System.Address); -- ./test.h:15
    pragma Import (C, test_display, "test_display");

end test_h;

Code block metadata
Project: Courses.Intro_To_Ada.Interfacing_With_C.C_Binds_3
MD5: 3bf8f01b94fd28594e4121a6a36af1f7

As we can see, the binding generator completely ignores the declaration struct test and all references to the test struct are replaced by addresses (System.Address). Nevertheless, these bindings are good enough to allow us to create a test application in Ada:

Listing 24: show_automatic_c_struct.bindings.adb

with Ada.Text_I0; use Ada.Text_I0;
with Interfaces.C;
use Interfaces.C;
with Interfaces.C.Strings;
use Interfaces.C.Strings;
with test_h; use test_h;
with System;

procedure Show_Automatic_C_Struct_Bindings is
    Name : constant chars_ptr :=
        New_String ("John Doe");
    Address : constant chars_ptr :=
        New_String ("Small Town");
    T : System.Address := test_create;
begin
    test_reset (T);

(continues on next page)
We can successfully bind our C code with Ada using the automatically-generated bindings, but they aren't ideal. Instead, we would prefer Ada bindings that match our (human) interpretation of the C header file. This requires manual analysis of the header file. The good news is that we can use the automatic generated bindings as a starting point and adapt them to our needs. For example, we can:

1. Define a Test type based on System.Address and use it in all relevant functions.
2. Remove the test_ prefix in all operations on the Test type.

This is the resulting specification:

```ada
with System;
with Interfaces.C; use Interfaces.C;
with Interfaces.C.Strings;

package adapted_test_h is

  type Test is new System.Address;

  function Create return Test;
  pragma Import (C, Create, "test_create");

  procedure Destroy (T : Test);
  pragma Import (C, Destroy, "test_destroy");

  procedure Reset (T : Test);
  pragma Import (C, Reset, "test_reset");

  procedure Set_Name (T : Test;
    Name : Interfaces.C.Strings.chars_ptr);
  pragma Import (C, Set_Name, "test_set_name");

  procedure Set_Address (T : Test;
    Address : Interfaces.C.Strings.chars_ptr);
  pragma Import (C, Set_Address, "test_set_address");

  procedure Display (T : Test);
  pragma Import (C, Display, "test_display");

end adapted_test_h;
```

And this is the corresponding Ada body:
with Interfaces.C;
use Interfaces.C;

with Interfaces.C.Strings;
use Interfaces.C.Strings;

with adapted_test_h; use adapted_test_h;

with System;

procedure Show_Adapted_C_Struct_Bindings is

  Name : constant chars_ptr := New_String ("John Doe");
  Address : constant chars_ptr := New_String ("Small Town");
  T : Test := Create;

begin
  Reset (T);
  Set_Name (T, Name);
  Set_Address (T, Address);
  Display (T);
  Destroy (T);
end Show_Adapted_C_Struct_Bindings;

Now we can use the Test type and its operations in a clean, readable way.
OBJECT-ORIENTED PROGRAMMING

Object-oriented programming (OOP) is a large and ill-defined concept in programming languages and one that tends to encompass many different meanings because different languages often implement their own vision of it, with similarities and differences from the implementations in other languages.

However, one model mostly "won" the battle of what object-oriented means, if only by sheer popularity. It's the model used in the Java programming language, which is very similar to the one used by C++. Here are some defining characteristics:

- Type derivation and extension: Most object-oriented languages allow the user to add fields to derived types.
- Subtyping: Objects of a type derived from a base type can, in some instances, be substituted for objects of the base type.
- Runtime polymorphism: Calling a subprogram, usually called a method, attached to an object type can dispatch at runtime depending on the exact type of the object.
- Encapsulation: Objects can hide some of their data.
- Extensibility: People from the "outside" of your package, or even your whole library, can derive from your object types and define their own behaviors.

Ada dates from before object-oriented programming was as popular as it is today. Some of the mechanisms and concepts from the above list were in the earliest version of Ada even before what we would call OOP was added:

- As we saw, encapsulation is not implemented at the type level in Ada, but instead at the package level.
- Subtyping can be implemented using, well, subtypes, which have a full and permissive static substitutability model. The substitution will fail at runtime if the dynamic constraints of the subtype are not fulfilled.
- Runtime polymorphism can be implemented using variant records.

However, this list leaves out type extensions, if you don't consider variant records, and extensibility.

The 1995 revision of Ada added a feature filling the gaps, which allowed people to program following the object-oriented paradigm in an easier fashion. This feature is called tagged types.

Note: It's possible to program in Ada without ever creating tagged types. If that's your preferred style of programming or you have no specific use for tagged types, feel free to not use them, as is the case for many features of Ada.

However, they can be the best way to express solutions to certain problems and they may be the best way to solve your problem. If that's the case, read on!
18.1 Derived types

Before presenting tagged types, we should discuss a topic we have brushed on, but not really covered, up to now:

You can create one or more new types from every type in Ada. Type derivation is built into the language.

Listing 1: newtypes.ads

```ada
package Newtypes is
    type Point is record
        X, Y : Integer;
    end record;

    type New_Point is new Point;
end Newtypes;
```

Code block metadata

Project: Courses.Intro_To_Ada.Object_Oriented_Programming.Newtypes
MD5: 0d45096755b4bfb08ba8db19ecba3f57

Type derivation is useful to enforce strong typing because the type system treats the two types as incompatible.

But the benefits are not limited to that: you can inherit things from the type you derive from. You not only inherit the representation of the data, but you can also inherit behavior.

When you inherit a type you also inherit what are called primitive operations. A primitive operation (or just a primitive) is a subprogram attached to a type. Ada defines primitives as subprograms defined in the same scope as the type.

Attention: A subprogram will only become a primitive of the type if:
1. The subprogram is declared in the same scope as the type and
2. The type and the subprogram are declared in a package

Listing 2: primitives.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Primitives is
    package Week is
        type Days is (Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday);

        -- Print_Day is a primitive of the type Days
        -- procedure Print_Day (D : Days);
        end Week;

    package body Week is
        procedure Print_Day (D : Days) is
            begin
                Put_Line (Days'Image (D));
            end Print_Day;
    end Week;
```

(continues on next page)
use Week;
type Weekend_Days is new
  Days range Saturday .. Sunday;

-- A procedure Print_Day is automatically
-- inherited here. It is as if the procedure
-- has been declared with the same body

Sat : Weekend_Days := Saturday;
beg
  Print_Day (Sat);
end Primitives;

This kind of inheritance can be very useful, and is not limited to record types (you can use it on discrete types, as in the example above), but it's only superficially similar to object-oriented inheritance:

- Records can't be extended using this mechanism alone. You also can't specify a new representation for the new type: it will always have the same representation as the base type.
- There's no facility for dynamic dispatch or polymorphism. Objects are of a fixed, static type.

There are other differences, but it's not useful to list them all here. Just remember that this is a kind of inheritance you can use if you only want to statically inherit behavior without duplicating code or using composition, but a kind you can't use if you want any dynamic features that are usually associated with OOP.

### 18.2 Tagged types

The 1995 revision of the Ada language introduced tagged types to fulfill the need for an unified solution that allows programming in an object-oriented style similar to the one described at the beginning of this chapter.

Tagged types are very similar to normal records except that some functionality is added:

- Types have a tag, stored inside each object, that identifies the runtime type\(^{20}\) of that object.
- Primitives can dispatch. A primitive on a tagged type is what you would call a method in Java or C++. If you derive a base type and override a primitive of it, you can often call it on an object with the result that which primitive is called depends on the exact runtime type of the object.

Subtyping rules are introduced allowing a tagged type derived from a base type to be statically compatible with the base type.

Let's see our first tagged type declarations:

```ada
package P is
  type My_Class is tagged null record;
  -- Just like a regular record, but
  -- with tagged qualifier
  -- Methods are outside of the type
  -- definition:
  procedure Foo (Self : in out My_Class);
  -- If you define a procedure taking a
  -- My_Class argument in the same package,
  -- it will be a method.
  -- Here's how you derive a tagged type:
  type Derived is new My_Class with record
    A : Integer;
    -- You can add fields in derived types.
  end record;
  overriding procedure Foo (Self : in out Derived);
  -- The "overriding" qualifier is optional,
  -- but if it is present, it must be valid.
end P;
```

```ada
with Ada.Text_IO; use Ada.Text_IO;
package body P is
  procedure Foo (Self : in out My_Class) is
    begin
      Put_Line ("In My_Class.Foo");
      end Foo;
  procedure Foo (Self : in out Derived) is
    begin
      Put_Line ("In Derived.Foo, A = "
                 & Integer'Image (Self.A));
    end Foo;
end P;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Object Oriented Programming.Tagged_Types

MD5: 45baad66a1047358addb574d0fa00bc
18.3 Classwide types

To remain consistent with the rest of the language, a new notation needed to be introduced to say "This object is of this type or any descendant derives tagged type".

In Ada, we call this the classwide type. It's used in OOP as soon as you need polymorphism. For example, you can't do the following:

Listing 5: main.adb

```ada
with P; use P;
procedure Main is
  O1 : My_Class;
    -- Declaring an object of type My_Class
  O2 : Derived := (A => 12);
    -- Declaring an object of type Derived
  O3 : My_Class := O2;
    -- INVALID: Trying to assign a value
    -- of type derived to a variable of
    -- type My_Class.
begin
  null;
end Main;
```

This is because an object of a type T is exactly of the type T, whether T is tagged or not. What you want to say as a programmer is "I want O3 to be able to hold an object of type My_Class or any type descending from My_Class". Here's how you do that:

Listing 6: main.adb

```ada
with P; use P;
procedure Main is
  O1 : My_Class;
    -- Declare an object of type My_Class
  O2 : Derived := (A => 12);
    -- Declare an object of type Derived
  O3 : My_Class'Class := O2;
    -- Now valid: My_Class'Class designates
    -- the classwide type for My_Class,
    -- which is the set of all types
    -- descending from My_Class (including
    -- My_Class).
begin
  null;
end Main;
```

(continues on next page)
Introduction to Ada

(continued from previous page)

null;
end Main;

18.4 Dispatching operations

We saw that you can override operations in types derived from another tagged type. The eventual goal of OOP is to make a dispatching call: a call to a primitive (method) that depends on the exact type of the object.

But, if you think carefully about it, a variable of type My_Class always contains an object of exactly that type. If you want to have a variable that can contain a My_Class or any derived type, it has to be of type My_Class'Class.

In other words, to make a dispatching call, you must first have an object that can be either of a type or any type derived from this type, namely an object of a classwide type.

Listing 7: main.adb

with P; use P;

procedure Main is
  01 : My_Class;
  -- Declare an object of type My_Class
  02 : Derived := (A => 12);
  -- Declare an object of type Derived
  03 : My_Class'Class := 02;
  04 : My_Class'Class := 01;
begin
  Foo (01);
  -- Non dispatching: Calls My_Class.Foo
  Foo (02);
  -- Non dispatching: Calls Derived.Foo
  Foo (03);
  -- Dispatching: Calls Derived.Foo
  Foo (04);
  -- Dispatching: Calls My_Class.Foo
end Main;

Attention: Because an object of a classwide type can be the size of any descendant of its base type, it has an unknown size. It's therefore an indefinite type, with the expected restrictions:

- It can't be stored as a field/component of a record
- An object of a classwide type needs to be initialized immediately (you can't specify the constraints of such a type in any way other than by initializing it).
Attention

You can convert an object of type Derived to an object of type My_Class. This is called a view conversion in Ada parlance and is useful, for example, if you want to call a parent method.

In that case, the object really is converted to a My_Class object, which means its tag is changed. Since tagged objects are always passed by reference, you can use this kind of conversion to modify the state of an object: changes to converted object will affect the original one.

Listing 8: main.adb

```ada
with P; use P;

procedure Main is
  O1 : Derived := (A => 12);
  -- Declare an object of type Derived
  O2 : My_Class := My_Class (O1);
  O3 : My_Class'Class := O2;
begin
  Foo (O1);
  -- Non dispatching: Calls Derived.Foo
  Foo (O2);
  -- Non dispatching: Calls My_Class.Foo
  Foo (O3);
  -- Dispatching: Calls My_Class.Foo
end Main;
```

Code block metadata

Project: Courses.Intro_To_Ada.Object_Oriented_Programming.Tagged_Types
MD5: b92112b05b01ff14789baca258fa0cbbc

Runtime output

In Derived.Foo, A = 12
In My_Class.Foo, A = 12
In My_Class.Foo

18.4. Dispatching operations
18.5 Dot notation

You can also call primitives of tagged types with a notation that's more familiar to object oriented programmers. Given the Foo primitive above, you can also write the above program this way:

Listing 9: main.adb

```ada
with P; use P;

procedure Main is
  01 : My_Class;
    -- Declare an object of type My_Class

  02 : Derived := (A => 12);
    -- Declare an object of type Derived

  03 : My_Class'Class := 02;

  04 : My_Class'Class := 01;
begin
  01.Foo;
    -- Non dispatching: Calls My_Class.Foo

  02.Foo;
    -- Non dispatching: Calls Derived.Foo

  03.Foo;
    -- Dispatching: Calls Derived.Foo

  04.Foo;
    -- Dispatching: Calls My_Class.Foo
end Main;
```

Code block metadata

Project: Courses.Intro_To_Ada.Object_Oriented_Programming.Tagged_Types
MD5: 9c6ebdfec9ceeb986d92eb90ec9ff59b

Runtime output

In My_Class.Foo
In Derived.Foo, A = 12
In Derived.Foo, A = 12
In My_Class.Foo

If the dispatching parameter of a primitive is the first parameter, which is the case in our examples, you can call the primitive using the dot notation. Any remaining parameter are passed normally:

Listing 10: main.adb

```ada
with P; use P;

procedure Main is
  package Extend is
    type D2 is new Derived with null record;
    procedure Bar (Self : in out D2; Val : Integer);
  end Extend;

  package body Extend is
    procedure Bar (Self : in out D2;

(continues on next page)
Val : Integer) is
begin
end Bar;
end Extend;
use Extend;
Obj := D2 := (A => 15);
begin
  Obj.Bar (2);
  Obj.Foo;
end Main;

18.6 Private & Limited

We've seen previously (in the Privacy (page 109) chapter) that types can be declared limited or private. These encapsulation techniques can also be applied to tagged types, as we'll see in this section.

This is an example of a tagged private type:

Listing 11: p.ads

package P is
  type T is tagged private;
private
  type T is tagged record
    E : Integer;
  end record;
end P;

This is an example of a tagged limited type:

Listing 12: p.ads

package P is
  type T is tagged limited record
    E : Integer;
  end record;
end P;

18.6. Private & Limited
Naturally, you can combine both *limited* and *private* types and declare a tagged limited private type:

**Listing 13: p.ads**

```ada
package P is
  type T is tagged limited private;
  procedure Init (A : in out T);
private
  type T is tagged limited record
    E : Integer;
  end record;
end P;
```

**Listing 14: p.adb**

```ada
package body P is
  procedure Init (A : in out T) is
    begin
      A.E := 0;
    end Init;
  end P;
```

**Listing 15: main.adb**

```ada
with P; use P;

procedure Main is
  T1, T2 : T;
begin
  T1.Init;
  T2.Init;
  -- The following line doesn't work
  -- because type T is private:
  --
  -- T1.E := 0;
  -- The following line doesn't work
  -- because type T is limited:
  --
  -- T2 := T1;
end Main;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Object_Oriented_Programming.Tagged_Limited_Private_Types
MD5: 68240374505bc9af7aad4e0baed3b9127b

Note that the code in the Main procedure above presents two assignments that trigger compilation errors because type T is limited private. In fact, you cannot:

- assign to T1.E directly because type T is private;
- assign T1 to T2 because type T is limited.
In this case, there's no distinction between tagged and non-tagged types: these compilation errors would also occur for non-tagged types.

### 18.7 Classwide access types

In this section, we'll discuss a useful pattern for object-oriented programming in Ada: classwide access type. Let's start with an example where we declare a tagged type \( T \) and a derived type \( T\_\text{New} \):

**Listing 16: p.ads**

```ada
package P is
  type T is tagged null record;
  procedure Show (Dummy : T);
  type T_New is new T with null record;
  procedure Show (Dummy : T_New);
end P;
```

**Listing 17: p.adb**

```ada
with Ada.Text_IO; use Ada.Text_IO;

package body P is
  procedure Show (Dummy : T) is
    begin
      Put_Line ("Using type " & T'External_Tag);
      end Show;

  procedure Show (Dummy : T_New) is
    begin
      Put_Line ("Using type " & T_New'External_Tag);
      end Show;
end P;
```

Note that we’re using null records for both types \( T \) and \( T\_\text{New} \). Although these types don’t actually have any component, we can still use them to demonstrate dispatching. Also note that the example above makes use of the \( \text{’External Tag} \) attribute in the implementation of the Show procedure to get a string for the corresponding tagged type.

As we’ve seen before, we must use a classwide type to create objects that can make dispatching calls. In other words, objects of type \( T'\text{Class} \) will dispatch. For example:

**Listing 18: dispatching_example.adb**

```ada
with P; use P;

procedure Dispatching_Example is
```

(continues on next page)
4             T2      :      T_New;
5          T_Dispatch : constant T'Class := T2;
6  begin
7          T_Dispatch.Show;
8  end Dispatching_Example;

A more useful application is to declare an array of objects that can dispatch. For example, we'd like to declare an array T_Arr, loop over this array and dispatch according to the actual type of each individual element:

```ada
for I in T_Arr'Range loop
    T_Arr (I).Show;
    -- Call Show procedure according
    -- to actual type of T_Arr (I)
end loop;
```

However, it's not possible to declare an array of type T'Class directly:

```ada
with P; use P;
procedure ClasswideCompilation_Error is
    T_Arr : array (1 .. 2) of T'Class;
    --
    -- Compilation Error!
begin
    for I in T_Arr'Range loop
        T_Arr (I).Show;
    end loop;
end ClasswideCompilation_Error;
```

In fact, it's impossible for the compiler to know which type would actually be used for each element of the array. However, if we use dynamic allocation via access types, we can allocate objects of different types for the individual elements of an array T_Arr. We do this by using classwide access types, which have the following format:

```ada
type T_Class is access T'Class;
```

We can rewrite the previous example using the T_Class type. In this case, dynamically allocated objects of this type will dispatch according to the actual type used during the
allocation. Also, let's introduce an Init procedure that won't be overridden for the derived T_New type. This is the adapted code:

Listing 20: p.ads

```ada
package P is
  type T is tagged record
    E : Integer;
  end record;

type T_Class is access T'class;

procedure Init (A : in out T);

procedure Show (Dummy : T);

type T_New is new T with null record;

procedure Show (Dummy : T_New);
end P;
```

Listing 21: p.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

package body P is

  procedure Init (A : in out T) is
  begin
    Put_Line ("Initializing type T...");
    A.E := 0;
  end Init;

  procedure Show (Dummy : T) is
  begin
    Put_Line ("Using type " & T'External_Tag);
  end Show;

  procedure Show (Dummy : T_New) is
  begin
    Put_Line ("Using type " & T_New'External_Tag);
  end Show;

end P;
```

Listing 22: main.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

with P; use P;

procedure Main is
  T_Arr : array (1 .. 2) of T_Class;
begin
  T_Arr (1) := new T;
  T_Arr (2) := new T_New;
  for I in T_Arr'Range loop
    Put_Line ("Element # " & Integer'Image (I));
  end loop;
```

(continues on next page)
In this example, the first element (T_Arr (1)) is of type T, while the second element is of type T_New. When running the example, the Init procedure of type T is called for both elements of the T_Arr array, while the call to the Show procedure selects the corresponding procedure according to the type of each element of T_Arr.
In previous chapters, we've used arrays as the standard way to group multiple objects of a specific data type. In many cases, arrays are good enough for manipulating those objects. However, there are situations that require more flexibility and more advanced operations. For those cases, Ada provides support for containers — such as vectors and sets — in its standard library.

We present an introduction to containers here. For a list of all containers available in Ada, see Appendix B (page 267).

19.1 Vectors

In the following sections, we present a general overview of vectors, including instantiation, initialization, and operations on vector elements and vectors.

19.1.1 Instantiation

Here's an example showing the instantiation and declaration of a vector V:

```
with Ada.Containers.Vectors;
procedure Show_Vector_Inst is
package Integer_Vectors is new
  Ada.Containers.Vectors
  (Index_Type => Natural,
   Element_Type => Integer);
V : Integer_Vectors.Vector;
begin
  null;
end Show_Vector_Inst;
```

Containers are based on generic packages, so we can't simply declare a vector as we would declare an array of a specific type:

```
A : array (1 .. 10) of Integer;
```
Instead, we first need to instantiate one of those packages. We with the container package (Ada.Containers.Vectors in this case) and instantiate it to create an instance of the generic package for the desired type. Only then can we declare the vector using the type from the instantiated package. This instantiation needs to be done for any container type from the standard library.

In the instantiation of Integer_Vectors, we indicate that the vector contains elements of Integer type by specifying it as the Element_Type. By setting Index_Type to Natural, we specify that the allowed range includes all natural numbers. We could have used a more restrictive range if desired.

### 19.1.2 Initialization

One way to initialize a vector is from a concatenation of elements. We use the & operator, as shown in the following example:

```
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Init is
  package Integer_Vectors is new Ada.Containers.Vectors
    (Index_Type => Natural,
     Element_Type => Integer);

  use Integer_Vectors;

  V : Vector := 20 & 10 & 0 & 13;
begin
  Put_Line("Vector has 
    & Count_Type'Image (V.Length)
    & "elements");
end Show_Vector_Init;
```

We specify use Integer_Vectors, so we have direct access to the types and operations from the instantiated package. Also, the example introduces another operation on the vector: Length, which retrieves the number of elements in the vector. We can use the dot notation because Vector is a tagged type, allowing us to write either V.Length or Length (V).
19.1.3 Appending and prepending elements

You add elements to a vector using the Prepend and Append operations. As the names suggest, these operations add elements to the beginning or end of a vector, respectively. For example:

Listing 3: show_vector_append.adb

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Append is

   package Integer_Vectors is new
     Ada.Containers.Vectors
     (Index_Type      => Natural,
      Element_Type    => Integer);

   use Integer_Vectors;

   V : Vector;

begin
   Put_Line ("Appending some elements 
     & "to the vector...");
   V.Append (20);  
   V.Append (10);  
   V.Append (0);   
   V.Append (13);  
   Put_Line ("Finished appending.");

   Put_Line ("Prepending some elements"
     & "to the vector...");
   V.Prepend (30); 
   V.Prepend (40); 
   V.Prepend (100); 
   Put_Line ("Finished prepending.");

   Put_Line ("Vector has "
     & Count_Type'Image (V.Length)
     & " elements");

end Show_Vector_Append;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Vector_Append
MD5: f88d393ba96a7950f58d9f1c0c74a021

Runtime output

Appending some elements to the vector...
Finished appending.
Prepending some elements to the vector...
Finished prepending.
Vector has 7 elements

This example puts elements into the vector in the following sequence: (100, 40, 30, 20, 10, 0, 13).

The Reference Manual specifies that the worst-case complexity must be:

- \( O(\log N) \) for the Append operation, and
• O(N log N) for the Prepend operation.

19.1.4 Accessing first and last elements

We access the first and last elements of a vector using the First_Element and Last_Element functions. For example:

Listing 4: show_vector_first_last_element.adb

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_First_Last_Element is

package Integer_Vectors is new
  Ada.Containers.Vectors
    (Index_Type => Natural,
     Element_Type => Integer);

use Integer_Vectors;

function Img (I : Integer) return String renames Integer'Image;
function Img (I : Count_Type) return String renames Count_Type'Image;

V : Vector := 20 & 10 & 0 & 13;
begin
  Put_Line ("Vector has 
    & Img (V.Length) 
    & " elements");
  -- Using V.First_Element to 
  -- retrieve first element
  Put_Line ("First element is 
    & Img (V.First_Element));
  -- Using V.Last_Element to 
  -- retrieve last element
  Put_Line ("Last element is 
    & Img (V.Last_Element));
end Show_Vector_First_Last_Element;
```

You can swap elements by calling the procedure Swap and retrieving a reference (a cursor) to the first and last elements of the vector by calling First and Last. A cursor allows us to iterate over a container and process individual elements from it.

With these operations, we’re able to write code to swap the first and last elements of a vector:
Introduction to Ada

Listing 5: show_vector_first_last_element.adb

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_First_Last_Element is

   package Integer_Vectors is new Ada.Containers.Vectors
      (Index_Type  => Natural,
       Element_Type => Integer);

   use Integer_Vectors;

   function Img (I : Integer) return String renames Integer'Image;

   V : Vector := 20 & 10 & 0 & 13;

   begin
      -- We use V.First and V.Last to retrieve
      -- cursor for first and last elements.
      -- We use V.Swap to swap elements.
      V.Swap (V.First, V.Last);

      Put_Line ("First element is now " & Img (V.First_Element));
      Put_Line ("Last element is now " & Img (V.Last_Element));
   end Show_Vector_First_Last_Element;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Vector_First_Last_Element
MD5: 1a0c0bf28bb661b3f328473ac3c2eb54

Runtime output

```
First element is now 13
Last element is now 20
```

19.1.5 Iterating

The easiest way to iterate over a container is to use a for E of Our_Container loop. This gives us a reference (E) to the element at the current position. We can then use E directly. For example:

Listing 6: show_vector_iteration.adb

```ada
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Iteration is

   package Integer_Vectors is new Ada.Containers.Vectors
      (Index_Type  => Natural,
       Element_Type => Integer);

   V : Vector := 20 & 10 & 0 & 13;

   begin
      for E in V.First .. V.Last loop
         Put_Line ("Current element is " & Img (E));
      end loop;
   end Show_Vector_Iteration;
```

(continues on next page)
Introduction to Ada

(continued from previous page)

Element_Type => Integer);

use Integer_Vectors;

function Img (I : Integer) return String
renames Integer’Image;

V : Vector := 20 & 10 & 0 & 13;
begin
  Put_Line ("Vector elements are: ");
  -- Using for ... of loop to iterate:
  for E of V loop
    Put_Line ("- " & Img (E));
  end loop;
end Show_Vector_Iteration;

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Vector_Iteration
MD5: 4fc9a939aa822097d3a937646d3e2910

Runtime output

Vector elements are:
- 20
- 10
- 0
- 13

This code displays each element from the vector V.

Because we’re given a reference, we can display not only the value of an element but also modify it. For example, we could easily write a loop to add one to each element of vector V:

for E of V loop
  E := E + 1;
end loop;

We can also use indices to access vector elements. The format is similar to a loop over array elements: we use a for I in <range> loop. The range is provided by V.First_Index and V.Last_Index. We can access the current element by using it as an array index: V (I). For example:

Listing 7: show_vector_index_iteration.adb

```ada
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;
procedure Show_Vector_Index_Iteration is
  package Integer_Vectors is new
    Ada.Containers.Vectors
      (Index_Type => Natural,
       Element_Type => Integer);
```

(continues on next page)
use Integer_Vectors;

V : Vector := 20 & 10 & 0 & 13;
begin
  Put_Line ("Vector elements are: ");
  --
  -- Using indices in a "for I in ..." loop
  -- to iterate:
  --
  for I in V.First_Index .. V.Last_Index loop
    -- Displaying current index I
    Put ("- [" & Extended_Index'Image (I) & "] ");
    Put (Integer'Image (V (I)));
    New_Line;
  end loop;
end Show_Vector_Index_Iteration;

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Vector_Index_Iteration
MD5: f5600bbcc53d6d6887a771b1505676e9

Runtime output

Vector elements are:
  - [ 0] 20
  - [ 1] 10
  - [ 2] 0
  - [ 3] 13

Here, in addition to displaying the vector elements, we’re also displaying each index, I, just like what we can do for array indices. Also, we can access the element by using either the short form V (I) or the longer form V.Element (I) but not V.I.

As mentioned in the previous section, you can use cursors to iterate over containers. For this, use the function Iterate, which retrieves a cursor for each position in the vector. The corresponding loop has the format for C in V.Iterate loop. Like the previous example using indices, you can again access the current element by using the cursor as an array index: V (C). For example:

Listing 8: show_vector_cursor_iteration.adb

with Ada.Containers.Vectors;

with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Cursor_Iteration is
  package Integer_Vectors is new
    Ada.Containers.Vectors
      (Index_Type => Natural,

19.1. Vectors 205
Element_Type => Integer);

use Integer_Vectors;

V : Vector := 20 & 10 & 0 & 13;
begin
  Put_Line ("Vector elements are: ");
  -- Use a cursor to iterate in a loop:
  for C in V.Iterate loop
    Put ("- [ ")
    & Extended_Index'Image (To_Index (C))
    & "] ");
    Put (Integer'Image (V (C)));
    New_Line;
  end loop;
end Show_Vector_Cursor_Iteration;

Instead of accessing an element in the loop using V (C), we could also have used the longer form Element (C). In this example, we're using the function To_Index to retrieve the index corresponding to the current cursor.

As shown in the comments after the loop, we could also use a while ... loop to iterate over the vector. In this case, we would start with a cursor for the first element (retrieved by calling V.First) and then call Next (C) to retrieve a cursor for subsequent elements.
Next (C) returns No_Element when the cursor reaches the end of the vector.

You can directly modify the elements using a reference. This is what it looks like when using both indices and cursors:

```
-- Modify vector elements using index
for I in V.First_Index .. V.Last_Index loop
    V (I) := V (I) + 1;
end loop;

-- Modify vector elements using cursor
for C in V.Iterate loop
    V (C) := V (C) + 1;
end loop;
```

The Reference Manual requires that the worst-case complexity for accessing an element be O(log N).

Another way of modifying elements of a vector is using a process procedure, which takes an individual element and does some processing on it. You can call Update_Element and pass both a cursor and an access to the process procedure. For example:

```
Listing 9: show_vector_update.adb

with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Update is
    package Integer_Vectors is new
        Ada.Containers.Vectors
        (Index_Type => Natural,
         Element_Type => Integer);
    use Integer_Vectors;

    procedure Add_One (I : in out Integer) is
    begin
        I := I + 1;
    end Add_One;

    V : Vector := 20 & 10 & 12;
    begin
        -- Use V.Update_Element to process elements
        for C in V.Iterate loop
            V.Update_Element (C, Add_One'Access);
        end loop;
    end Show_Vector_Update;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Vector_Update
MD5: 5dcc3dd8020632a8ea2ce975ecd8f4da
19.1.6 Finding and changing elements

You can locate a specific element in a vector by retrieving its index. Find_Index retrieves the index of the first element matching the value you’re looking for. Alternatively, you can use Find to retrieve a cursor referencing that element. For example:

Listing 10: show_find_vector_element.adb

```ada
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Find_Vector_Element is

   package Integer_Vectors is new Ada.Containers.Vectors
   (Index_Type => Natural,
    Element_Type => Integer);

   use Integer_Vectors;

   V : Vector := 20 & 10 & 0 & 13;
   Idx : Extended_Index;
   C : Cursor;

   begin
      -- Using Find_Index to retrieve the index
      -- of element with value 10
      Idx := V.Find_Index (10);
      Put_Line ("Index of element with value 10 is " & Extended_Index'Image (Idx));

      -- Using Find to retrieve the cursor for
      -- the element with value 13
      C := V.Find (13);
      Idx := To_Index (C);
      Put_Line ("Index of element with value 13 is " & Extended_Index'Image (Idx));
   end Show_Find_Vector_Element;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Find_Vector_Element
MD5: c3da01cd66c8705a7cbccae8390d5f81

Runtime output

Index of element with value 10 is 1
Index of element with value 13 is 3

As we saw in the previous section, we can directly access vector elements by using either an index or cursor. However, an exception is raised if we try to access an element with an invalid index or cursor, so we must check whether the index or cursor is valid before using it to access an element. In our example, Find_Index or Find might not have found the element in the vector. We check for this possibility by comparing the index to No_Index or the cursor to No_Element. For example:

```ada
-- Modify vector element using index
if Idx /= No_Index then
   V (Idx) := 11;
end if;
```

(continues on next page)
Instead of writing \( V(C) := 14 \), we could use the longer form \( V.Replace_Element(C, 14) \).

### 19.1.7 Inserting elements

In the previous sections, we've seen examples of how to add elements to a vector:

- using the concatenation operator (\&\&) at the vector declaration, or
- calling the \texttt{Prepend} and \texttt{Append} procedures.

You may want to insert an element at a specific position, e.g. before a certain element in the vector. You do this by calling \texttt{Insert}. For example:

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Insert is
  package Integer_Vectors is new
    Ada.Containers.Vectors
    (Index_Type      => Natural,
     Element_Type    => Integer);
  use Integer_Vectors;

  procedure Show.Elements (V : Vector) is
  begin
    New_Line;
    Put_Line ("Vector has " & Count_Type'Image (V.Length) & " elements");
    if not V.Is_Empty then
      Put_Line ("Vector elements are: ");
      for E of V loop
        Put_Line ("- " & Integer'Image (E));
      end loop;
    end if;
    Show.Elements (V);
    V : Vector := 20 & 10 & 12;
    C : Cursor;
    begin
      Show.Elements (V);
      New_Line;
      Put_Line ("Adding element with value 9");
      Put_Line (" (before 10)...");  
```

(continues on next page)
In this example, we're looking for an element with the value of 10. If we find it, we insert an element with the value of 9 before it.

### 19.1.8 Removing elements

You can remove elements from a vector by passing either a valid index or cursor to the Delete procedure. If we combine this with the functions Find_Index and Find from the previous section, we can write a program that searches for a specific element and deletes it, if found:

Listing 12: show_remove_vector_element.adb

```ada
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Remove_Vector_Element is
    package Integer_Vectors is new
        Ada.Containers.Vectors
            (Index_Type => Natural,
             Element_Type => Integer);
    use Integer_Vectors;
```

(continues on next page)
12  V : Vector := 20 & 10 & 0 & 13 & 10 & 13;
13  Idx : Extended_Index;
14  C : Cursor;
15  begin
16    -- Use Find_Index to retrieve index of
17    -- the element with value 10
18    Idx := V.Find_Index (10);
19
20    -- Checking whether index is valid
21    if Idx /= No_Index then
22      -- Removing element using V.Delete
23      V.Delete (Idx);
24    end if;
25
26    -- Use Find to retrieve cursor for
27    -- the element with value 13
28    C := V.Find (13);
29
30    -- Check whether index is valid
31    if C /= No_Element then
32      -- Remove element using V.Delete
33      V.Delete (C);
34    end if;
35  end Show_Remove_Vector_Element;

We can extend this approach to delete all elements matching a certain value. We just need to keep searching for the element in a loop until we get an invalid index or cursor. For example:

Listing 13: show_remove_vector_elements.adb

with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Remove_Vector_Elements is
  package Integer_Vectors is new
    Ada.Containers.Vectors
      (Index_Type    => Natural,
       Element_Type => Integer);

  use Integer_Vectors;

  procedure Show_Elements (V : Vector) is
    begin
      New_Line;
      Put_Line ("Vector has 
        & Count_Type'Image (V.Length)
        & " elements");
      if not V.Is_Empty then
        Put_Line ("Vector elements are: ");
for E of V loop
  Put_Line ("- " & Integer’Image (E));
end loop;
end if;
end Show_Elements;

V : Vector := 20 & 10 & 0 & 13 & 10 & 14 & 13;
begin
  Show_Elements (V);
  -- Remove elements using an index
  --
  declare
    E : constant Integer := 10;
    I : Extended_Index;
  begin
    New_Line;
    Put_Line ("Removing all elements with value of " & Integer’Image (E) & "...");
    loop
      I := V.Find_Index (E);
      exit when I = No_Index;
      V.Delete (I);
    end loop;
  end;
  -- Remove elements using a cursor
  --
  declare
    E : constant Integer := 13;
    C : Cursor;
  begin
    New_Line;
    Put_Line ("Removing all elements with value of " & Integer’Image (E) & "...");
    loop
      C := V.Find (E);
      exit when C = No_Element;
      V.Delete (C);
    end loop;
  end;
  Show_Elements (V);
end Show_Remove_Vector_Elements;
Removing all elements with value of 10...

Removing all elements with value of 13...

Vector has 3 elements
Vector elements are:
- 20
- 0
- 14

In this example, we remove all elements with the value 10 from the vector by retrieving their index. Likewise, we remove all elements with the value 13 by retrieving their cursor.

**19.1.9 Other Operations**

We've seen some operations on vector elements. Here, we'll see operations on the vector as a whole. The most prominent is the concatenation of multiple vectors, but we'll also see operations on vectors, such as sorting and sorted merging operations, that view the vector as a sequence of elements and operate on the vector considering the element's relations to each other.

We do vector concatenation using the `&` operator on vectors. Let's consider two vectors V1 and V2. We can concatenate them by doing `V := V1 & V2`. V contains the resulting vector.

The generic package `Generic_Sorting` is a child package of `Ada.Containers.Vectors`. It contains sorting and merging operations. Because it's a generic package, you can't use it directly, but have to instantiate it. In order to use these operations on a vector of integer values (`Integer_Vectors`, in our example), you need to instantiate it directly as a child of `Integer_Vectors`. The next example makes it clear how to do this.

After instantiating `Generic_Sorting`, we make all the operations available to us with the `use` statement. We can then call `Sort` to sort the vector and `Merge` to merge one vector into another.

The following example presents code that manipulates three vectors (V1, V2, V3) using the concatenation, sorting and merging operations:

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Vectors;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Vector_Ops is

    package Integer_Vectors is new
        Ada.Containers.Vectors
        (Index_Type  => Natural,
         Element_Type => Integer);

    package Integer_Vectors_Sorting is
        new Integer_Vectors.Generic_Sorting;

(continues on next page)
use Integer_Vectors;
use Integer_Vectors_Sorting;

procedure Show_Elements (V : Vector) is
begin
New_Line;
Put_Line ("Vector has \\" & Count_Type'Image (V.Length)
& "] elements");

if not V.Is_Empty then
Put_Line ("Vector elements are: ");
for E of V loop
Put_Line (" - " & Integer'Image (E));
end loop;
end if;
end Show_Elements;

V, V1, V2, V3 : Vector;
begin
V1 := 10 & 12 & 18;
V2 := 11 & 13 & 19;
V3 := 15 & 19;
New_Line;
Put_Line ("---- V1 ----");
Show_Elements (V1);

New_Line;
Put_Line ("---- V2 ----");
Show_Elements (V2);

New_Line;
Put_Line ("---- V3 ----");
Show_Elements (V3);
New_Line;
Put_Line ("Concatenating V1, V2 and V3 into V: ");
V := V1 & V2 & V3;
Show_Elements (V);
New_Line;
Put_Line ("Sorting V: ");
Sort (V);
Show_Elements (V);
New_Line;
Put_Line ("Merging V2 into V1: ");
Merge (V1, V2);
Show_Elements (V1);
end Show_Vector_Ops;

Code block metadata
Runtime output

---- V1 ----
Vector has 3 elements
Vector elements are:
- 10
- 12
- 18

---- V2 ----
Vector has 3 elements
Vector elements are:
- 11
- 13
- 19

---- V3 ----
Vector has 2 elements
Vector elements are:
- 15
- 19

Concatenating V1, V2 and V3 into V:
Vector has 8 elements
Vector elements are:
- 10
- 11
- 12
- 13
- 18
- 19
- 15
- 19

Sorting V:
Vector has 8 elements
Vector elements are:
- 10
- 11
- 12
- 13
- 15
- 18
- 19
- 19

Merging V2 into V1:
Vector has 6 elements
Vector elements are:
- 10
- 11
- 12

(continues on next page)
The Reference Manual requires that the worst-case complexity of a call to `Sort` be $O(N^2)$ and the average complexity be better than $O(N^2)$.

## 19.2 Sets

Sets are another class of containers. While vectors allow duplicated elements to be inserted, sets ensure that no duplicated elements exist.

In the following sections, we'll see operations you can perform on sets. However, since many of the operations on vectors are similar to the ones used for sets, we'll cover them more quickly here. Please refer back to the section on vectors for a more detailed discussion.

### 19.2.1 Initialization and iteration

To initialize a set, you can call the `Insert` procedure. However, if you do, you need to ensure no duplicate elements are being inserted: if you try to insert a duplicate, you'll get an exception. If you have less control over the elements to be inserted so that there may be duplicates, you can use another option instead:

- a version of `Insert` that returns a Boolean value indicating whether the insertion was successful;
- the `Include` procedure, which silently ignores any attempt to insert a duplicated element.

To iterate over a set, you can use a `for E of S` loop, as you saw for vectors. This gives you a reference to each element in the set.

Let's see an example:

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Ordered_Sets;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Set_Init is

package Integer_Sets is new
   Ada.Containers.Ordered_Sets
      (Element_Type => Integer);

use Integer_Sets;

S : Set;
-- Same as:  S : Integer_Sets.Set;
C : Cursor;
Ins : Boolean;

begin
   S.Insert (20);
   S.Insert (10);
```

(continues on next page)
S.Insert (0);
S.Insert (13);
-- Calling S.Insert(0) now would raise
-- Constraint_Error because this element
-- is already in the set. We instead call a
-- version of Insert that doesn't raise an
-- exception but instead returns a Boolean
-- indicating the status
S.Insert (0, C, Ins);
if not Ins then
  Put_Line
    ("Error while inserting 0 into set");
end if;
-- We can also call S.Include instead
-- If the element is already present,
-- the set remains unchanged
S.Include (0);
S.Include (13);
S.Include (14);
Put_Line ("Set has 
  & Count_Type'Image (S.Length) 
  & " elements");
-- Iterate over set using for .. of loop
Put_Line ("Elements:");
for E of S loop
  Put_Line ("- " & Integer'Image (E));
end loop;
end Show_Set_Init;

Code block metadata
Project: Courses.Intro_To_Ada.Standard_Library.Show_Set_Init
MD5: b87f6729f6a278396347248b95a30cb6

Runtime output
Error while inserting 0 into set
Set has 5 elements
Elements:
  - 0
  - 10
  - 13
  - 14
  - 20
19.2.2 Operations on elements

In this section, we briefly explore the following operations on sets:

- Delete and Exclude to remove elements;
- Contains and Find to verify the existence of elements.

To delete elements, you call the procedure Delete. However, analogously to the Insert procedure above, Delete raises an exception if the element to be deleted isn't present in the set. If you want to permit the case where an element might not exist, you can call Exclude, which silently ignores any attempt to delete a non-existent element.

Contains returns a Boolean value indicating whether a value is contained in the set. Find also looks for an element in a set, but returns a cursor to the element or No_Element if the element doesn't exist. You can use either function to search for elements in a set.

Let's look at an example that makes use of these operations:

Listing 16: show_set_element_ops.adb

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Ordered_Sets;
with Ada.Text_IO; use Ada.Text_IO;
procedure Show_Set_Element_Ops is
  package Integer_Sets is new
    Ada.Containers.Ordered_Sets
    (Element_Type => Integer);
  use Integer_Sets;
  procedure Show_Elements (S : Set) is
    begin
      New_Line;
      Put_Line ("Set has ", & Count_Type'Image (S.Length) & " elements");
      Put_Line ("Elements:");
      for E of S loop
        Put_Line (": " & Integer'Image (E));
      end loop;
    end Show_Elements;
  S : Set;
  begin
    S.Insert (20);
    S.Insert (10);
    S.Insert (0);
    S.Insert (13);
    S.Delete (13);
    -- Calling S.Delete (13) again raises
    -- Constraint_Error because the element
    -- is no longer present in the set, so
    -- it can't be deleted. We can call
    -- V.Exclude instead:
    S.Exclude (13);
    if S.Contains (20) then
      Put_Line ("Found element 20 in set");
    end if;
```
(continues on next page)
end if;
-- Alternatively, we could use S.Find
-- instead of S.Contains
if S.Find (0) /= No_Element then
  Put_Line ("Found element 0 in set");
end if;
Show_Elements (S);
end Show_Set_Element_Ops;

Code block metadata

Project: Courses.Intro To Ada.Standard_Library.Show_Set_Element_Ops
MD5: 77fb2aaba4221e337b0f90dd1a49c556

Runtime output

Found element 20 in set
Found element 0 in set
Set has 3 elements
Elements:
- 0
- 10
- 20

In addition to ordered sets used in the examples above, the standard library also offers
hashed sets. The Reference Manual requires the following average complexity of each
operation:

<table>
<thead>
<tr>
<th>Operations</th>
<th>Ordered_Sets</th>
<th>Hashed_Sets</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Insert</td>
<td>O((log N)^2) or better</td>
<td>O(log N)</td>
</tr>
<tr>
<td>• Include</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Replace</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Delete</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Exclude</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Find</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Subprogram using cursor</td>
<td>O(1)</td>
<td>O(1)</td>
</tr>
</tbody>
</table>

19.2.3 Other Operations

The previous sections mostly dealt with operations on individual elements of a set. But
Ada also provides typical set operations: union, intersection, difference and symmetric
difference. In contrast to some vector operations we've seen before (e.g. Merge), here
you can use built-in operators, such as -. The following table lists the operations and its
associated operator:

<table>
<thead>
<tr>
<th>Set Operation</th>
<th>Operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>Union</td>
<td>or</td>
</tr>
<tr>
<td>Intersection</td>
<td>and</td>
</tr>
<tr>
<td>Difference</td>
<td>-</td>
</tr>
<tr>
<td>Symmetric difference</td>
<td>xor</td>
</tr>
</tbody>
</table>
The following example makes use of these operators:

Listing 17: show_set_ops.adb

```ada
with Ada.Containers; use Ada.Containers;
with Ada.Containers.Ordered_Sets;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Set_Ops is

package Integer_Sets is new
   Ada.Containers.Ordered_Sets
      (Element_Type => Integer);

use Integer_Sets;

procedure Show_Elements (S : Set) is
begin
   Put_Line ("Elements:");
   for E of S loop
      Put_Line ("- " & Integer'Image (E));
   end loop;
end Show_Elements;

procedure Show_Op (S : Set;
                   Op_Name : String) is
begin
   New_Line;
   Put_Line (Op_Name & "(set #1, set #2) has 
              " & Integer'Image (S.Length) & 
              " elements");
end Show_Op;

S1, S2, S3 : Set;
begin
   S1.Insert (0);
   S1.Insert (10);
   S1.Insert (13);
   S2.Insert (0);
   S2.Insert (10);

19.3 Indefinite maps

The previous sections presented containers for elements of definite types. Although most examples in those sections presented Integer types as element type of the containers, containers can also be used with indefinite types, an example of which is the String type. However, indefinite types require a different kind of containers designed specially for them.

We'll also be exploring a different class of containers: maps. They associate a key with a specific value. An example of a map is the one-to-one association between a person and their age. If we consider a person’s name to be the key, the value is the person’s age.

19.3.1 Hashed maps

Hashed maps are maps that make use of a hash as a key. The hash itself is calculated by a function you provide.

In other languages

Hashed maps are similar to dictionaries in Python and hashes in Perl. One of the main differences is that these scripting languages allow using different types for the values contained in a single map, while in Ada, both the type of key and value are specified in the package instantiation and remains constant for that specific map. You can't have a map where two elements are of different types or two keys are of different types. If you want to use multiple types, you must create a different map for each and use only one type in each map.

When instantiating a hashed map from Ada.Containers.Indefinite_Hashed_Maps, we specify following elements:

- Key_Type: type of the key
- Element_Type: type of the element
- Hash: hash function for the Key_Type
- Equivalent_Keys: an equality operator (e.g. =) that indicates whether two keys are to be considered equal.
  - If the type specified in Key_Type has a standard operator, you can use it, which you do by specifying that operator as the value of Equivalent_Keys.

In the next example, we'll use a string as a key type. We'll use the Hash function provided by the standard library for strings (in the Ada.Strings package) and the standard equality operator.

You add elements to a hashed map by calling Insert. If an element is already contained in a map M, you can access it directly by using its key. For example, you can change the value of an element by calling M ("My_Key") := 10. If the key is not found, an exception
is raised. To verify if a key is available, use the function Contains (as we've seen above in the section on sets).

Let's see an example:

Listing 18: show_hashed_map.adb

```ada
with Ada.Containers.Indefinite_Hashed_Maps;
with Ada.Strings.Hash;

with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Hashed_Map is

   package Integer_Hashed_Maps is new
      Ada.Containers.Indefinite_Hashed_Maps
         (Key_Type => String,
          Element_Type => Integer,
          Hash => Ada.Strings.Hash,
          Equivalent_Keys => "=");

   use Integer_Hashed_Maps;

   M : Map;
   -- Same as:
   -- M : Integer_Hashed_Maps.Map;
   begin
      M.Include ("Alice", 24);
      M.Include ("John", 40);
      M.Include ("Bob", 28);

      if M.Contains ("Alice") then
         Put_Line ("Alice's age is "
               & Integer'Image (M ("Alice")));
      end if;

      -- Update Alice's age
      -- Key must already exist in M.
      -- Otherwise an exception is raised.
      M ("Alice") := 25;

      New_Line; Put_Line ("Name & Age:");
      for C in M.Iterate loop
         Put_Line (Key (C) & ": "
               & Integer'Image (M (C)));
      end loop;

   end Show_Hashed_Map;
```

Name & Age:
John: 40
Bob: 28
Alice: 25

19.3. Indefinite maps
19.3.2 Ordered maps

Ordered maps share many features with hashed maps. The main differences are:

- A hash function isn’t needed. Instead, you must provide an ordering function (< operator), which the ordered map will use to order elements and allow fast access, O(log N), using a binary search.

- If the type specified in Key_Type has a standard < operator, you can use it in a similar way as we did for Equivalent_Keys above for hashed maps.

Let’s see an example:

Listing 19: show_ordered_map.adb

```ada
with Ada.Containers.Indefinite_Ordered_Maps;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Ordered_Map is
  package Integer_Ordered_Maps is new
    Ada.Containers.Indefinite_Ordered_Maps
    (Key_Type => String,
     Element_Type => Integer);
  use Integer_Ordered_Maps;

  M : Map;

  begin
    M.Include ("Alice", 24);
    M.Include ("John", 40);
    M.Include ("Bob", 28);

    if M.Contains ("Alice") then
      Put_Line ("Alice's age is ",
                & Integer'Image (M ("Alice")));
    end if;

    -- Update Alice's age
    -- Key must already exist in M
    M ("Alice") := 25;

    New_Line; Put_Line ("Name & Age:");
    for C in M.Iterate loop
      Put_Line (Key (C) & ": ",
                & Integer'Image (M (C)));
    end loop;
  end Show_Ordered_Map;
```

Code block metadata

Runtime output

Alice's age is 24
Name & Age:
Alice: 25
(continues on next page)
You can see a great similarity between the examples above and from the previous section. In fact, since both kinds of maps share many operations, we didn't need to make extensive modifications when we changed our example to use ordered maps instead of hashed maps. The main difference is seen when we run the examples: the output of a hashed map is usually unordered, but the output of a ordered map is always ordered, as implied by its name.

**19.3.3 Complexity**

Hashed maps are generally the fastest data structure available to you in Ada if you need to associate heterogeneous keys to values and search for them quickly. In most cases, they are slightly faster than ordered maps. So if you don't need ordering, use hashed maps.

The Reference Manual requires the following average complexity of operations:

<table>
<thead>
<tr>
<th>Operations</th>
<th>Ordered_Maps</th>
<th>Hashed_Maps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>O((log N)^2) or better</td>
<td>O(log N)</td>

</tr>
<tr>
<td>Exclude</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Find</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Subprogram using cursor | O(1) | O(1) |
The standard library supports processing of dates and times using two approaches:

- Calendar approach, which is suitable for handling dates and times in general;
- Real-time approach, which is better suited for real-time applications that require enhanced precision — for example, by having access to an absolute clock and handling time spans. Note that this approach only supports times, not dates.

The following sections present these two approaches.

## 20.1 Date and time handling

The Ada.Calendar package supports handling of dates and times. Let's look at a simple example:

Listing 1: display_current_time.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Calendar; use Ada.Calendar;
with Ada.Calendar.Formatting; use Ada.Calendar.Formatting;

procedure Display_Current_Time is
    Now : Time := Clock;
begin
    Put_Line ("Current time: " & Image (Now));
end Display_Current_Time;
```

This example displays the current date and time, which is retrieved by a call to the Clock function. We call the function Image from the Ada.Calendar.Formatting package to get a String for the current date and time. We could instead retrieve each component using the Split function. For example:
**Introduction to Ada**

Listing 2: display_current_year.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Calendar; use Ada.Calendar;

procedure Display_Current_Year is
  Now : Time := Clock;

  Now_Year : Year_Number;
  Now_Month : Month_Number;
  Now_Day : Day_Number;
  Now_Seconds : Day_Duration;

begin
  Split (Now,
    Now_Year,
    Now_Month,
    Now_Day,
    Now_Seconds);

  Put_Line ("Current year is: ",
    & Year_Number'Image (Now_Year));
  Put_Line ("Current month is: ",
    & Month_Number'Image (Now_Month));
  Put_Line ("Current day is: ",
    & Day_Number'Image (Now_Day));
end Display_Current_Year;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Display_Current_Year
MD5: fdf298ee97f225261ce3839ebd833bbe

Runtime output

Current year is: 2024
Current month is: 6
Current day is: 30

Here, we're retrieving each element and displaying it separately.

### 20.1.1 Delaying using date

You can delay an application so that it restarts at a specific date and time. We saw something similar in the chapter on tasking. You do this using a `delay until` statement. For example:

Listing 3: display_delay_next_specific_time.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Calendar; use Ada.Calendar;

with Ada.Calendar.Formatting;
use Ada.Calendar.Formatting;

with Ada.Calendar.Time_Zones;
use Ada.Calendar.Time_Zones;

procedure Display_Delay_Next_Specific_Time is

  TZ : Time_Offset := UTC_Time_Offset;
  Next : Time    :=
```

(continues on next page)
In this example, we specify the date and time by initializing Next using a call to Time_Of, a function taking the various components of a date (year, month, etc) and returning an element of the Time type. Because the date specified is in the past, the delay until statement won't produce any noticeable effect. However, if we passed a date in the future, the program would wait until that specific date and time arrived.

Here we're converting the time to the local timezone. If we don't specify a timezone, Coordinated Universal Time (abbreviated to UTC) is used by default. By retrieving the time offset to UTC with a call to UTC_Time_Offset from the Ada.Calendar.Time_Zones package, we can initialize TZ and use it in the call to Time_Of. This is all we need do to make the information provided to Time_Of relative to the local time zone.

We could achieve a similar result by initializing Next with a String. We can do this with a call to Value from the Ada.Calendar.Formatting package. This is the modified code:

```ada
procedure Display_Delay_Next_Specific_Time is
    TZ : Time_Offset := UTC_Time_Offset;
begin
    Put_Line ("Let's wait until...");
    Put_Line (Image (Next, True, TZ));
    delay until Next;
    Put_Line ("Enough waiting!");
end Display_Delay_Next_Specific_Time;
```

Listing 4: display_delay_next_specific_time.adb

---

20.1. Date and time handling
Introduction to Ada

Next :=
Ada.Calendar.Formatting.Value
("2018-05-01 15:00:00.00", TZ);

begin
Put_Line ("Let's wait until...");
Put_Line (Image (Next, True, TZ));
delay until Next;
Put_Line ("Enough waiting!");
end Display_Delay_Next_Specific_Time;

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Display_Delay_Next_Specific_Time
MD5: fdf6ad7fca303d4d7bd444c23e11c7bd

Runtime output

Let's wait until...
2018-05-01 15:00:00.00
Enough waiting!

In this example, we're again using TZ in the call to Value to adjust the input time to the current time zone.

In the examples above, we were delaying to a specific date and time. Just like we saw in the tasking chapter, we could instead specify the delay relative to the current time. For example, we could delay by 5 seconds, using the current time:

Listing 5: display_delay_next.adb

with Ada.Calendar; use Ada.Calendar;
with Ada.Text_IO; use Ada.Text_IO;

procedure Display_Delay_Next is
  D : Duration := 5.0;
  -- ^ seconds
  Now : Time := Clock;
  Next : Time := Now + D;
  -- ^ use duration to
  -- specify next
  -- point in time
begin
  Put_Line ("Let's wait "
    & Duration'Image (D)
    & " seconds...");
delay until Next;
  Put_Line ("Enough waiting!");
end Display_Delay_Next;

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Display_Delay_Next
MD5: 58360d93388c3fe027c39d67389efc7

Runtime output
Let's wait 5.000000000 seconds...
Enough waiting!

Here, we're specifying a duration of 5 seconds in D, adding it to the current time from Now, and storing the sum in Next. We then use it in the delay until statement.

## 20.2 Real-time

In addition to Ada.Calendar, the standard library also supports time operations for real-time applications. These are included in the Ada.Real_Time package. This package also include a Time type. However, in the Ada.Real_Time package, the Time type is used to represent an absolute clock and handle a time span. This contrasts with the Ada.Calendar, which uses the Time type to represent dates and times.

In the previous section, we used the Time type from the Ada.Calendar and the delay until statement to delay an application by 5 seconds. We could have used the Ada.Real_Time package instead. Let's modify that example:

Listing 6: display_delay_next_real_time.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Real_Time; use Ada.Real_Time;

procedure Display_Delay_Next_Real_Time is
  D : Time_Span := Seconds (5);
  Next : Time := Clock + D;
begin
  Put_Line ("Let's wait 
            & Duration'Image (To_Duration (D))
            & " seconds...");
  delay until Next;
  Put_Line ("Enough waiting!");
end Display_Delay_Next_Real_Time;
```

The main difference is that D is now a variable of type Time_Span, defined in the Ada.Real_Time package. We call the function Seconds to initialize D, but could have gotten a finer granularity by calling Nanoseconds instead. Also, we need to first convert D to the Duration type using To_Duration before we can display it.
20.2.1 Benchmarking

One interesting application using the Ada.Real_Time package is benchmarking. We've used that package before in a previous section when discussing tasking. Let's look at an example of benchmarking:

Listing 7: display_benchmarking.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Real_Time; use Ada.Real_Time;
procedure Display_Benchmarking is
  procedure Computational_Intensive_App is
  begin
    delay 5.0;
  end Computational_Intensive_App;
  begin
    Start_Time, Stop_Time : Time;
    Elapsed_Time : Time_Span;
  begin
    Start_Time := Clock;
    Computational_Intensive_App;
    Stop_Time := Clock;
    Elapsed_Time := Stop_Time - Start_Time;
    Put_Line ("Elapsed time: 
      & Duration'Image
      (To_Duration (Elapsed_Time))
      & " seconds");
  end Display_Benchmarking;
end
```

This example defines a dummy Computational_Intensive_App implemented using a simple delay statement. We initialize Start_Time and Stop_Time from the then-current clock and calculate the elapsed time. By running this program, we see that the time is roughly 5 seconds, which is expected due to the delay statement.

A similar application is benchmarking of CPU time. We can implement this using the Execution_Time package. Let's modify the previous example to measure CPU time:

Listing 8: display_benchmarking_cpu_time.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Real_Time; use Ada.Real_Time;
with Ada.Execution_Time; use Ada.Execution_Time;
procedure Display_Benchmarking_CPU_Time is
  procedure Computational_Intensive_App is
  begin
    Compute...
  end Computational_Intensive_App;
  begin
    Start_Time := Clock;
    Computational_Intensive_App;
    Stop_Time := Clock;
    Elapsed_Time := Stop_Time - Start_Time;
    Put_Line ("Elapsed time:
      & Duration'Image
      (To_Duration (Elapsed_Time))
      & " seconds");
  end Display_Benchmarking_CPU_Time;
end
```

This example defines a dummy Computational_Intensive_App implemented using a simple delay statement. We initialize Start_Time and Stop_Time from the then-current clock and calculate the elapsed time. By running this program, we see that the time is roughly 5 seconds, which is expected due to the delay statement.

A similar application is benchmarking of CPU time. We can implement this using the Execution_Time package. Let's modify the previous example to measure CPU time:
In this example, Start_Time and Stop_Time are of type CPU_Time instead of Time. However, we still call the Clock function to initialize both variables and calculate the elapsed time in the same way as before. By running this program, we see that the CPU time is significantly lower than the 5 seconds we've seen before. This is because the delay statement doesn't require much CPU time. The results will be different if we change the implementation of Computational_Intensive_App to use a mathematical function in a long loop. For example:

Listing 9: display_benchmarking_math.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Real_Time; use Ada.Real_Time;
with Ada.Execution_Time; use Ada.Execution_Time;
with Ada.Numerics.Generic_Elementary_Functions;

procedure Display_Benchmarking_Math is
    procedure Computational_Intensive_App is
        package Funcs is new
            Ada.Numerics.Generic_Elementary_Functions
            (Float_Type => Long_Long_Float);
        use Funcs;
        X : Long_Long_Float;
    begin
        for I in 0 .. 1_000_000 loop
            X := Tan (Arctan
                (Tan (Arctan
                    (Tan (Arctan
                        (Tan (Arctan
                            (Tan (Arctan
                                (Tan (Arctan
                                    (Tan (Arctan
                                        (Tan (Arctan
                                            (Tan (Arctan
                                                (Tan (Arctan
                                                    (Tan (Arctan
                                                        (Tan (Arctan
                                                            (Tan (Arctan
                                                                (Tan (Arctan
                                                                    (Tan (Arctan
                                                                        (Tan (Arctan
                                                                            (Tan (Arctan
                                                                                (Tan (Arctan
                                                                                    (Tan (Arctan
                                                                                        (Tan (Arctan
                                                                                            (Tan (Arctan
                                                                                                (Tan (Arctan
                                                                                                                                                   (Tan (Arctan
                                                                                                                                                      (Tan (Arctan
                                                                                                                                                          (Tan (Arctan
                                                                                   (continues on next page)
Now that our dummy `Computational_Intensive_App` involves mathematical operations requiring significant CPU time, the measured elapsed and CPU time are much closer to each other than before.
STANDARD LIBRARY: STRINGS

In previous chapters, we’ve seen source-code examples using the **String** type, which is a fixed-length string type — essentially, it’s an array of characters. In many cases, this data type is good enough to deal with textual information. However, there are situations that require more advanced text processing. Ada offers alternative approaches for these cases:

- **Bounded strings**: similar to fixed-length strings, bounded strings have a maximum length, which is set at its instantiation. However, bounded strings are not arrays of characters. At any time, they can contain a string of varied length — provided this length is below or equal to the maximum length.

- **Unbounded strings**: similar to bounded strings, unbounded strings can contain strings of varied length. However, in addition to that, they don’t have a maximum length. In this sense, they are very flexible.

The following sections present an overview of the different string types and common operations for string types.

### 21.1 String operations

Operations on standard (fixed-length) strings are available in the `Ada.Strings.Fixed` package. As mentioned previously, standard strings are arrays of elements of `Character` type with a fixed-length. That’s why this child package is called Fixed.

One of the simplest operations provided is counting the number of substrings available in a string (**Count**) and finding their corresponding indices (**Index**). Let’s look at an example:

Listing 1: show_find_substring.adb

```ada
with Ada.Strings.Fixed; use Ada.Strings.Fixed;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Find_Substring is
  S : String := "Hello" & 3 * " World";
  P : constant String := "World";
  Idx : Natural;
  Cnt : Natural;
begin
  Cnt := Ada.Strings.Fixed.Count (Source => S,
                                  Pattern => P);
  Put_Line ("String: " & S);
  Put_Line ("Count for ": " & Natural'Image (Cnt));
```

(continues on next page)
Idx := 0;
for I in 1 .. Cnt loop
    Idx := Index (Source => S,
    Pattern => P,
    From => Idx + 1);
    Put_Line ("Found instance of '" & P & "' at position: " & Natural'Image (Idx));
end loop;
end Show_Find_Substring;

Code block metadata

Project: Courses.Intro To Ada.Standard_Library.Show_Find_Substring
MD5: faa8373bf9ae9f9f5507cf55590b0c0

Runtime output

String: Hello World World World
Count for 'World': 3
Found instance of 'World' at position: 7
Found instance of 'World' at position: 13
Found instance of 'World' at position: 19

We initialize the string S using a multiplication. Writing "Hello" & 3 * " World" creates the string Hello World World World. We then call the function Count to get the number of instances of the word World in S. Next we call the function Index in a loop to find the index of each instance of World in S.

That example looked for instances of a specific substring. In the next example, we retrieve all the words in the string. We do this using Find_Token and specifying whitespaces as separators. For example:

Listing 2: show_find_words.adb

with Ada.Strings; use Ada.Strings;
with Ada.Strings.Fixed; use Ada.Strings.Fixed;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Find_Words is
    S : String := "Hello" & 3 * " World";
    F : Positive;
    L : Natural;
    I : Natural := 1;
    Whitespace : constant Character_Set := To_Set (' ');
begin
    Put_Line ("String: " & S);
    Put_Line ("String length: 
    & Integer'Image (S'Length));
    while I in S'Range loop
        Find_Token
        (Source => S,
        Set => Whitespace,
From => I,
Test => Outside,
First => F,
Last => L);

exit when L = 0;

Put_Line ("Found word instance at position ",
& Natural'Image (F)
& ";" & S (F .. L) & ";");
-- & "." & F'Img & "." & L'Img

I := L + 1;
end loop;
end Show_Find_Words;

---

We pass a set of characters to be used as delimitators to the procedure Find_Token. This set is a member of the Character_Set type from the Ada.Strings.Maps package. We call the To_Set function (from the same package) to initialize the set to Whitespace and then call Find_Token to loop over each valid index and find the starting index of each word. We pass Outside to the Test parameter of the Find_Token procedure to indicate that we're looking for indices that are outside the Whitespace set, i.e. actual words. The First and Last parameters of Find_Token are output parameters that indicate the valid range of the substring. We use this information to display the string (S (F .. L)).

The operations we've looked at so far read strings, but don't modify them. We next discuss operations that change the content of strings:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>Insert substring in a string</td>
</tr>
<tr>
<td>Overwrite</td>
<td>Overwrite a string with a substring</td>
</tr>
<tr>
<td>Delete</td>
<td>Delete a substring</td>
</tr>
<tr>
<td>Trim</td>
<td>Remove whitespaces from a string</td>
</tr>
</tbody>
</table>

All these operations are available both as functions or procedures. Functions create a new string but procedures perform the operations in place. The procedure will raise an exception if the constraints of the string are not satisfied. For example, if we have a string S containing 10 characters, inserting a string with two characters (e.g. "!!") into it produces a string containing 12 characters. Since it has a fixed length, we can't increase its size. One possible solution in this case is to specify that truncation should be applied while inserting the substring. This keeps the length of S fixed. Let's see an example that makes use of both function and procedure versions of Insert, Overwrite, and Delete:
with Ada.Strings; use Ada.Strings;
with Ada.Strings.Fixed; use Ada.Strings.Fixed;
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Adapted_Strings is
    S : String := "Hello World";
    P : constant String := "World";
    N : constant String := "Beautiful";

procedure Display_Adapted_String
    (Source : String;
     Before : Positive;
     New_Item : String;
     Pattern : String)
is
    S_Ins_In : String := Source;
    S_Ovr_In : String := Source;
    S_Del_In : String := Source;

    S_Ins : String :=
        Insert (Source,
                Before,
                New_Item & " ");
    S_Ovr : String :=
        Overwrite (Source,
                  Before,
                  New_Item);
    S_Del : String :=
        Trim (Delete (Source,
                     Before,
                     Before + Pattern'Length - 1),
                     Ada.Strings.Right);
begin
    Insert (S_Ins_In,
            Before,
            New_Item,
            Right);
    Overwrite (S_Ovr_In,
               Before,
               New_Item,
               Right);
    Delete (S_Del_In,
            Before,
            Before + Pattern'Length - 1);
    Put_Line ("Original: "
              & Source & ";");
    Put_Line ("Insert: "
              & S_Ins & ";");
    Put_Line ("Overwrite: "
              & S_Ovr & ";");
    Put_Line ("Delete: "
              & S_Del & ";");
    Put_Line ("Insert (in-place): "
(continues on next page)
21.2 Limitation of fixed-length strings

Using fixed-length strings is usually good enough for strings that are initialized when they are declared. However, as seen in the previous section, procedural operations on strings cause difficulties when done on fixed-length strings because fixed-length strings are arrays of characters. The following example shows how cumbersome the initialization of fixed-length strings can be when it's not performed in the declaration:

Listing 4: show_char_array.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
procedure Show_Char_Array is
   S : String (1 .. 15);  -- Strings are arrays of Character
begin
   S := "Hello ";
end Show_Char_Array;
```

In this example, we look for the index of the substring World and perform operations on this substring within the outer string. The procedure Display_Adapted_String uses both versions of the operations. For the procedural version of Insert and Overwrite, we apply truncation to the right side of the string (Right). For the Delete procedure, we specify the range of the substring, which is replaced by whitespaces. For the function version of Delete, we also call Trim which trims the trailing whitespace.
### 21.3 Bounded strings

Bounded strings are defined in the `Ada.Strings.Bounded.Generic_Bounded_Length` package. Because this is a generic package, you need to instantiate it and set the maximum length of the bounded string. You can then declare bounded strings of the `Bounded_String` type.

Both bounded and fixed-length strings have a maximum length that they can hold. However, bounded strings are not arrays, so initializing them at run-time is much easier. For example:

```ada
with Ada.Strings; use Ada.Strings;
with Ada.Strings.Bounded; use Ada.Text_IO;
procedure Show_Bounded_String is
  package B_Str is new
    Ada.Strings.Bounded.Generic_Bounded_Length
    (Max => 15);
  use B_Str;
```

In this case, we can't simply write `S := "Hello"` because the resulting array of characters for the `Hello` constant has a different length than the `S` string. Therefore, we need to include trailing whitespaces to match the length of `S`. As shown in the example, we could use an exact range for the initialization (`S (1 .. 5)`) or use an explicit array of individual characters.

When strings are initialized or manipulated at run-time, it's usually better to use bounded or unbounded strings. An important feature of these types is that they aren't arrays, so the difficulties presented above don't apply. Let's start with bounded strings.
procedure Display_String_Info
   (S : Bounded_String)
is
begin
   Put_Line ("String: " & To_String (S));
   Put_Line ("String Length: " & Integer’Image (Length (S)));
   -- String:
   -- S’Length => ok
   -- Bounded_String:
   -- S’Length => compilation error:
   -- bounded strings are
   -- not arrays!
   Put_Line ("Max. Length: " & Integer’Image (Max_Length));
end Display_String_Info;

begin
   S1 := To_Bounded_String ("Hello");
   Display_String_Info (S1);
   S2 := To_Bounded_String ("Hello World");
   Display_String_Info (S2);
   S1 := To_Bounded_String ("Something longer to say here...", Right);
   Display_String_Info (S1);
end Show_Bounded_String;

By using bounded strings, we can easily assign to S1 and S2 multiple times during execution. We use the To_Bounded_String and To_String functions to convert, in the respective direction, between fixed-length and bounded strings. A call to To_Bounded_String raises an exception if the length of the input string is greater than the maximum capacity of the bounded string. To avoid this, we can use the truncation parameter (Right in our example).

Bounded strings are not arrays, so we can't use the ‘Length attribute as we did for fixed-length strings. Instead, we call the Length function, which returns the length of the bounded string. The Max_Length constant represents the maximum length of the bounded string that we set when we instantiated the package.

After initializing a bounded string, we can manipulate it. For example, we can append
a string to a bounded string using `Append` or concatenate bounded strings using the `&` operator. Like so:

```ada
with Ada.Strings; use Ada.Strings;
with Ada.Strings.Bounded; use Ada.Text_IO;

procedure Show_Bounded_String_Op is
    package B_Str is new
        Ada.Strings.Bounded.Generic_Bounded_Length
            (Max => 30);
    use B_Str;

    S1, S2 : Bounded_String;

begin
    S1 := To_Bounded_String ("Hello");
    -- Alternatively:
    -- A := Null_Bounded_String & "Hello"
    Append (S1, " World");
    -- Alternatively:
    -- Append (A, " World", Right);
    Put_Line ("String: " & To_String (S1));

    S2 := To_Bounded_String ("Hello!");
    S1 := S1 & " " & S2;
    Put_Line ("String: " & To_String (S1));
end Show_Bounded_String_Op;
```

We can initialize a bounded string with an empty string using the `Null_Bounded_String` constant. Also, we can use the `Append` procedure and specify the truncation mode like we do with the `To_Bounded_String` function.

### 21.4 Unbounded strings

Unbounded strings are defined in the `Ada.Strings.Unbounded` package. This is not a generic package, so we don't need to instantiate it before using the `Unbounded_String` type. As you may recall from the previous section, bounded strings require a package instantiation.

Unbounded strings are similar to bounded strings. The main difference is that they can hold strings of any size and adjust according to the input string: if we assign, e.g., a 10-character string to an unbounded string and later assign a 50-character string, internal operations in the container ensure that memory is allocated to store the new string. In most cases, developers don't need to worry about these operations. Also, no truncation is necessary.
Initialization of unbounded strings is very similar to bounded strings. Let's look at an example:

Listing 7: show_unbounded_string.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Strings; use Ada.Strings;

procedure Show_Unbounded_String is
  S1, S2 : Unbounded_String;

  procedure Display_String_Info
    (S : Unbounded_String)
  is
    begin
      Put_Line ("String: " & To_String (S));
      Put_Line ("String Length: " & Integer'Image (Length (S)));
    end Display_String_Info;

begin
  S1 := To_Unbounded_String ("Hello");
  -- Alternatively:
  -- A := Null_Unbounded_String & "Hello";
  Display_String_Info (S1);

  S2 := To_Unbounded_String ("Hello World");
  Display_String_Info (S2);

  S1 := To_Unbounded_String ("Something longer to say here...");
  Display_String_Info (S1);
end Show_Unbounded_String;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Unbounded_String
MD5: 904402992c96eb393b875d1b7cf49c1b

Runtime output

String: Hello
String Length: 5
String: Hello World
String Length: 11
String: Something longer to say here...
String Length: 31

Like bounded strings, we can assign to S1 and S2 multiple times during execution and use the To_Unbounded_String and To_String functions to convert back-and-forth between fixed-length strings and unbounded strings. However, in this case, truncation is not needed.

And, just like for bounded strings, you can use the Append procedure and the & operator for unbounded strings. For example:

Listing 8: show_unbounded_string_op.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
(continues on next page)
```

21.4. Unbounded strings
Introduction to Ada

(continued from previous page)

```ada
with Ada.Strings.Unbounded;
use Ada.Strings.Unbounded;

procedure Show_Unbounded_String_Op is

   S1, S2 : Unbounded_String := Null_Unbounded_String;

begin
   S1 := S1 & "Hello";
   S2 := S2 & "Hello!";

   Append (S1, " World");
   Put_Line ("String: " & To_String (S1));

   S1 := S1 & " " & S2;
   Put_Line ("String: " & To_String (S1));

end Show_Unbounded_String_Op;
```

In this example, we're concatenating the unbounded `S1` and `S2` strings with the "Hello" and "Hello!" strings, respectively. Also, we're using the `Append` procedure, just like we did with bounded strings.
STANDARD LIBRARY: FILES AND STREAMS

Ada provides different approaches for file input/output (I/O):

- **Text I/O**, which supports file I/O in text format, including the display of information on the console.
- **Sequential I/O**, which supports file I/O in binary format written in a sequential fashion for a specific data type.
- **Direct I/O**, which supports file I/O in binary format for a specific data type, but also supporting access to any position of a file.
- **Stream I/O**, which supports I/O of information for multiple data types, including objects of unbounded types, using files in binary format.

This table presents a summary of the features we’ve just seen:

<table>
<thead>
<tr>
<th>File I/O option</th>
<th>Format</th>
<th>Random access</th>
<th>Data types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text I/O</td>
<td>text</td>
<td></td>
<td>string type</td>
</tr>
<tr>
<td>Sequential I/O</td>
<td>binary</td>
<td></td>
<td>single type</td>
</tr>
<tr>
<td>Direct I/O</td>
<td>binary</td>
<td>✓</td>
<td>single type</td>
</tr>
<tr>
<td>Stream I/O</td>
<td>binary</td>
<td>✓</td>
<td>multiple types</td>
</tr>
</tbody>
</table>

In the following sections, we discuss details about these I/O approaches.

### 22.1 Text I/O

In most parts of this course, we used the `Put_Line` procedure to display information on the console. However, this procedure also accepts a `File_Type` parameter. For example, you can select between standard output and standard error by setting this parameter explicitly:

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Std_Text_Out is
begin
  Put_Line (Standard_Output, "Hello World #1");
  Put_Line (Standard_Error, "Hello World #2");
end Show_Std_Text_Out;
```

**Code block metadata**

- **Project**: Courses.Intro_To_Ada.Standard_Library.Show_Std_Text_Out
- **MD5**: 4d75bd2906226897244e3d2a611c9725
Runtime output

Hello World #1
Hello World #2

You can also use this parameter to write information to any text file. To create a new file for writing, use the Create procedure, which initializes a File_Type element that you can later pass to Put_Line (instead of, e.g., Standard_Output). After you finish writing information, you can close the file by calling the Close procedure.

You use a similar method to read information from a text file. However, when opening the file, you must specify that it's an input file (In_File) instead of an output file. Also, instead of calling the Put_Line procedure, you call the Get_Line function to read information from the file.

Let's see an example that writes information into a new text file and then reads it back from the same file:

Listing 2: show_simple_text_file_io.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Simple_Text_File_IO is
  F : File_Type;
  File_Name : constant String := "simple.txt"
begin
  Create (F, Out_File, File_Name);
  Put_Line (F, "Hello World #1");
  Put_Line (F, "Hello World #2");
  Put_Line (F, "Hello World #3");
  Close (F);
  Open (F, In_File, File_Name);
  while not End_Of_File (F) loop
    Put_Line (Get_Line (F));
  end loop;
  Close (F);
end Show_Simple_Text_File_IO;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Simple_Text_File_IO
MD5: 7461e946eef18c93219fa4ce3afbb1e

Runtime output

Hello World #1
Hello World #2
Hello World #3

In addition to the Create and Close procedures, the standard library also includes a Reset procedure, which, as the name implies, resets (erases) all the information from the file. For example:

Listing 3: show_text_file_reset.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Text_File_Reset is
  F : File_Type;
  File_Name : constant String := "simple.txt"
begin
  Reset (F, File_Name);
end Show_Text_File_Reset;
```

(continues on next page)
Create (F, Out_File, File_Name);
Put_Line (F, "Hello World #1");
Reset (F);
Put_Line (F, "Hello World #2");
Close (F);

Open (F, In_File, File_Name);
while not End_Of_File (F) loop
  Put_Line (Get_Line (F));
end loop;
Close (F);
end Show_Text_File_Reset;

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Text_File_Reset
MD5: 5e5498f03b2c829513af062c5959fc93

Runtime output

Hello World #2

By running this program, we notice that, although we’ve written the first string ("Hello World #1") to the file, it has been erased because of the call to Reset.

In addition to opening a file for reading or writing, you can also open an existing file and append to it. Do this by calling the Open procedure with the Append_File option.

When calling the Open procedure, an exception is raised if the specified file isn’t found. Therefore, you should handle exceptions in that context. The following example deletes a file and then tries to open the same file for reading:

Listing 4: show_text_file_input_except.adb

with Ada.Text_IO; use Ada.Text_IO;

procedure Show_Text_File_Input_Except is
  F : File_Type;
  File_Name : constant String := "simple.txt";
begin
  -- Open output file and delete it
  Create (F, Out_File, File_Name);
  Delete (F);
  -- Try to open deleted file
  Open (F, In_File, File_Name);
  Close (F);
exception
  when Name_Error =>
    Put_Line ("File does not exist");
  when others =>
    Put_Line ("Error while processing input file");
end Show_Text_File_Input_Except;

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Text_File_Input_Except
MD5: c8d257091831c48d10b6e70e34b4261b

Runtime output
**Introduction to Ada**

File does not exist

In this example, we create the file by calling `Create` and then delete it by calling `Delete`. After the call to `Delete`, we can no longer use the `File_Type` element. After deleting the file, we try to open the non-existent file, which raises a `Name_Error` exception.

### 22.2 Sequential I/O

The previous section presented details about text file I/O. Here, we discuss doing file I/O in binary format. The first package we'll explore is the `Ada.Sequential_IO` package. Because this package is a generic package, you need to instantiate it for the data type you want to use for file I/O. Once you've done that, you can use the same procedures we've seen in the previous section: `Create`, `Open`, `Close`, `Reset` and `Delete`. However, instead of calling the `Get_Line` and `Put_Line` procedures, you'd call the `Read` and `Write` procedures.

In the following example, we instantiate the `Ada.Sequential_IO` package for floating-point types:

```ada
with Ada.Text_IO;
with Ada.Sequential_IO;

procedure Show_Seq_Float_IO is
  package Float_IO is
    new Ada.Sequential_IO (Float);
    use Float_IO;
  F : Float_IO.File_Type;
  File_Name : constant String :=
    "float_file.bin";
begin
  Create (F, Out_File, File_Name);
  Write (F, 1.5);
  Write (F, 2.4);
  Write (F, 6.7);
  Close (F);

  declare
    Value : Float;
  begin
    Open (F, In_File, File_Name);
    while not End_Of_File (F) loop
      Read (F, Value);
      Ada.Text_IO.Put_Line
        (Float'Image (Value));
    end loop;
    Close (F);
  end Show_Seq_Float_IO;
```

**Code block metadata**

Project: Courses.Intro_To_Ada.Standard_Library.Show_Seq_Float_IO
MD5: 27aa5daf92c4ba5df23f535c3578aa34

**Runtime output**

Chapter 22. Standard library: Files and streams
We use the same approach to read and write complex information. The following example uses a record that includes a Boolean and a floating-point value:

Listing 6: show_seq_rec_io.adb

```ada
with Ada.Text_IO;
with Ada.Sequential_IO;

procedure Show_Seq_Rec_IO is
  type Num_Info is record
    Valid : Boolean := False;
    Value : Float;
  end record;

  procedure Put_Line (N : Num_Info) is
  begin
    if N.Valid then
      Ada.Text_IO.Put_Line
      ("(ok, " & Float'Image (N.Value) & ")");
    else
      Ada.Text_IO.Put_Line
      ("(not ok, ----------)");
    end if;
  end Put_Line;

  package Num_Info_IO is new Ada.Sequential_IO (Num_Info);
  use Num_Info_IO;

  F : Num_Info_IO.File_Type;
  File_Name : constant String := "float_file.bin";
begin
  Create (F, Out_File, File_Name);
  Write (F, (True, 1.5));
  Write (F, (False, 2.4));
  Write (F, (True, 6.7));
  Close (F);

  declare
    Value : Num_Info;
  begin
    Open (F, In_File, File_Name);
    while not End_Of_File (F) loop
      Read (F, Value);
      Put_Line (Value);
    end loop;
    Close (F);
  end Show_Seq_Rec_IO;
end Show_Seq_Rec_IO;
```

Code block metadata

Project: Courses.Intro_To_Ada.Standard_Library.Show_Seq_Rec_IO
MD5: a88b1428cc50745dce0509087e74adb7

Runtime output
As the example shows, we can use the same approach we used for floating-point types to perform file I/O for this record. Once we instantiate the Ada.Sequential_IO package for the record type, file I/O operations are performed the same way.

22.3 Direct I/O

Direct I/O is available in the Ada.Direct_IO package. This mechanism is similar to the sequential I/O approach just presented, but allows us to access any position in the file. The package instantiation and most operations are very similar to sequential I/O. To rewrite the Show_Seq_Float_IO application presented in the previous section to use the Ada.Direct_IO package, we just need to replace the instances of the Ada.Sequential_IO package by the Ada.Direct_IO package. This is the new source code:

Listing 7: show_dir_float_io.adb

```ada
with Ada.Text_IO;
with Ada.Direct_IO;

procedure Show_Dir_Float_IO is
  package Float_IO is new Ada.Direct_IO(Float);
  use Float_IO;

  F : Float_IO.File_Type;
  File_Name : constant String := "float_file.bin";
  begin
    Create (F, Out_File, File_Name);
    Write (F, 1.5);
    Write (F, 2.4);
    Write (F, 6.7);
    Close (F);

    declare
      Value : Float;
    begin
      Open (F, In_File, File_Name);
      while not End_Of_File (F) loop
        Read (F, Value);
        Ada.Text_IO.Put_Line ("Float'Image (Value));
      end loop;
      Close (F);
    end Show_Dir_Float_IO;
```

Runtime output

1.50000E+00
2.40000E+00
6.70000E+00
Unlike sequential I/O, direct I/O allows you to access any position in the file. However, it doesn't offer an option to append information to a file. Instead, it provides an Inout_File mode allowing reading and writing to a file via the same File_Type element.

To access any position in the file, call the Set_Index procedure to set the new position/index. You can use the Index function to retrieve the current index. Let's see an example:

Listing 8: show_dir_float_in_out_file.adb

```ada
with Ada.Text_IO;
with Ada.Direct_IO;

procedure Show_Dir_Float_In_Out_File is
   package Float_IO is new Ada.Direct_IO (Float);
   use Float_IO;

   F : Float_IO.File_Type;
   File_Name : constant String := "float_file.bin";

   begin
      -- Open file for input / output
      Create (F, Inout_File, File_Name);
      Write (F, 1.5);
      Write (F, 2.4);
      Write (F, 6.7);

      -- Set index to previous position
      -- and overwrite value
      Set_Index (F, Index (F) - 1);
      Write (F, 7.7);

      declare
         Value : Float;
      begin
         -- Set index to start of file
         Set_Index (F, 1);

         while not End_Of_File (F) loop
            Read (F, Value);
            Ada.Text_IO.Put_Line (Float'Image (Value));
         end loop;

         Close (F);
      end Show_Dir_Float_In_Out_File;
```

By running this example, we see that the file contains 7.7, rather than the previous 6.7 that we wrote. We overwrote the value by changing the index to the previous position before doing another write.

In this example we used the Inout_File mode. Using that mode, we just changed the index back to the initial position before reading from the file (Set_Index (F, 1)) instead
of closing the file and reopening it for reading.

22.4 Stream I/O

All the previous approaches for file I/O in binary format (sequential and direct I/O) are specific for a single data type (the one we instantiate them with). You can use these approaches to write objects of a single data type that may be an array or record (potentially with many fields), but if you need to create and process files that include different data types, or any objects of an unbounded type, these approaches are not sufficient. Instead, you should use stream I/O.

Stream I/O shares some similarities with the previous approaches. We still use the Create, Open and Close procedures. However, instead of accessing the file directly via a File_Type element, you use a Stream_Access element. To read and write information, you use the 'Read or 'Write attributes of the data types you're reading or writing.

Let's look at a version of the Show.Dir.Float.IO procedure from the previous section that makes use of stream I/O instead of direct I/O:

Listing 9: show_float_stream.adb

```ada
with Ada.Text_IO;
with Ada.Streams.Stream_IO;
use Ada.Streams.Stream_IO;

procedure Show_Float_Stream is
  F : File_Type;
  S : Stream_Access;
  File_Name : constant String := "float_file.bin";
begin
  Create (F, Out_File, File_Name);
  S := Stream (F);
  Float'Write (S, 1.5);
  Float'Write (S, 2.4);
  Float'Write (S, 6.7);

  Close (F);

  declare
    Value : Float;
  begin
    Open (F, In_File, File_Name);
    S := Stream (F);

    while not End_Of_File (F) loop
      Float'Read (S, Value);
      Ada.Text_IO.Put_Line (Float'Image (Value));
    end loop;
  end;
end Show_Float_Stream;
```

Code block metadata

MD5: 34ccf04b0821074a332019ac0e38bb3e
After the call to Create, we retrieve the corresponding Stream_Access element by calling the Stream function. We then use this stream to write information to the file via the 'Write attribute of the Float type. After closing the file and reopening it for reading, we again retrieve the corresponding Stream_Access element and processed to read information from the file via the 'Read attribute of the Float type.

You can use streams to create and process files containing different data types within the same file. You can also read and write unbounded data types such as strings. However, when using unbounded data types you must call the 'Input and 'Output attributes of the unbounded data type: these attributes write information about bounds or discriminants in addition to the object's actual data.

The following example shows file I/O that mixes both strings of different lengths and floating-point values:

Listing 10: show_string_stream.adb

```ada
with Ada.Text_IO;

with Ada.Streams.Stream_IO;
use Ada.Streams.Stream_IO;

procedure Show_String_Stream is
    F : File_Type;
    S : Stream_Access;
    File_Name : constant String := "float_file.bin";

    procedure Output (S : Stream_Access;
                          FV : Float;
                          SV : String) is
        begin
            String'Output (S, SV);
            Float'Output (S, FV);
        end Output;

    procedure Input_Display (S : Stream_Access) is
        SV : String := String'Input (S);
        FV : Float := Float'Input (S);
        begin
            Ada.Text_IO.Put_Line (Float'Image (FV)
                                  & " --- " & SV);
        end Input_Display;

    begin
        Create (F, Out_File, File_Name);
        S := Stream (F);
        Output (S, 1.5, "Hi!!");
        Output (S, 2.4, "Hello world!");
        Output (S, 6.7, "Something longer here...");
        Close (F);
        Open (F, In_File, File_Name);
        S := Stream (F);
    end Show_String_Stream;
```
When you use Stream I/O, no information is written into the file indicating the type of the data that you wrote. If a file contains data from different types, you must reference types in the same order when reading a file as when you wrote it. If not, the information you get will be corrupted. Unfortunately, strong data typing doesn’t help you in this case. Writing simple procedures for file I/O (as in the example above) may help ensuring that the file format is consistent.

Like direct I/O, stream I/O support also allows you to access any location in the file. However, when doing so, you need to be extremely careful that the position of the new index is consistent with the data types you’re expecting.
STANDARD LIBRARY: NUMERICS

The standard library provides support for common numeric operations on floating-point types as well as on complex types and matrices. In the sections below, we present a brief introduction to these numeric operations.

23.1 Elementary Functions

The Ada.Numerics.Elementary_Functions package provides common operations for floating-point types, such as square root, logarithm, and the trigonometric functions (e.g., sin, cos). For example:

Listing 1: show_elem_math.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Numerics; use Ada.Numerics;
with Ada.Numerics.Elementary_Functions;
use Ada.Numerics.Elementary_Functions;

procedure Show_Elem_Math is
  X : Float;
begin
  X := 2.0;
  Put_Line ("Square root of "
             & Float'Image (X)
             & " is "
             & Float'Image (Sqrt (X)));
  X := e;
  Put_Line ("Natural log of "
             & Float'Image (X)
             & " is "
             & Float'Image (Log (X)));
  X := 10.0 ** 6.0;
  Put_Line ("Log_10 of "
             & Float'Image (X)
             & " is "
             & Float'Image (Log (X, 10.0)));
  X := 2.0 ** 8.0;
  Put_Line ("Log_2 of "
             & Float'Image (X)
             & " is "
             & Float'Image (Log (X, 2.0)));
```

(continues on next page)
Ada 3.4

X := Pi;
Put_Line ("Cos of " & Float'Image (X) & " is " & Float'Image (Cos (X)));

X := -1.0;
Put_Line ("Arccos of " & Float'Image (X) & " is " & Float'Image (Arccos (X)));
end Show_Elem_Math;

Here we use the standard e and Pi constants from the Ada.Numerics package.

The Ada.Numerics.Elementary_Functions package provides operations for the Float type. Similar packages are available for Long_Float and Long_Long_Float types. For example, the Ada.Numerics.Long_Elementary_Functions package offers the same set of operations for the Long_Float type. In addition, the Ada.Numerics.Generic_Elementary_Functions package is a generic version of the package that you can instantiate for custom floating-point types. In fact, the Elementary_Functions package can be defined as follows:

```
package Elementary_Functions is new
   Ada.Numerics.Generic_Elementary_Functions (Float);
```

## 23.2 Random Number Generation

The Ada.Numerics.Float_Random package provides a simple random number generator for the range between 0.0 and 1.0. To use it, declare a generator G, which you pass to Random. For example:

```
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Numerics.Float_Random;
use Ada.Numerics.Float_Random;

procedure Show_Float_Random_Num is
   G : Generator;
   X : Uniformly_Distributed;
begin
```

(continues on next page)
Some random numbers between 0.00000E+00 and 1.00000E+00:
9.74383E-01
3.73925E-01
7.63879E-01
2.70624E-01
5.32957E-02
1.24468E-01
4.45997E-01
9.39235E-01
3.75469E-01
7.85886E-01
4.37336E-01
4.67083E-01
9.41378E-01
1.42369E-01
5.85918E-01

The standard library also includes a random number generator for discrete numbers, which is part of the Ada.Numerics.Discrete_Random package. Since it's a generic package, you have to instantiate it for the desired discrete type. This allows you to specify a range for the generator. In the following example, we create an application that displays random integers between 1 and 10:

Listing 3: show_discrete_random_num.adb

```ada
with Ada.Text_IO; use Ada.Text_IO;
with Ada.Numerics.Discrete_Random;

procedure Show_Discrete_Random_Num is
    subtype Random_Range is Integer range 1 .. 10;
    package R is new
        Ada.Numerics.Discrete_Random (Random_Range);
    use R;
    G : Generator;
    X : Random_Range;
begin
```

(continues on next page)
Reset (G);

Put_Line ("Some random numbers between ",
  & Integer'Image (Random_Range'First)
  & " and "
  & Integer'Image (Random_Range'Last)
  & ":");

for I in 1 .. 15 loop
  X := Random (G);
  Put_Line (Integer'Image (X));
end loop;
end Show_Discrete_Random_Num;

Here, package R is instantiated with the Random_Range type, which has a constrained range between 1 and 10. This allows us to control the range used for the random numbers. We could easily modify the application to display random integers between 0 and 20 by changing the specification of the Random_Range type. We can also use floating-point or fixed-point types.

23.3 Complex Types

The Ada.Numerics.Complex_Types package provides support for complex number types and the Ada.Numerics.Complex_Elementary_Functions package provides support for common operations on complex number types, similar to the Ada.Numerics.Elementary_Functions package. Finally, you can use the Ada.Text_IO.Complex_IO package to perform I/O operations on complex numbers. In the following example, we declare variables of the Complex type and initialize them using an aggregate:

Listing 4: show_elem_math.adb

with Ada.Text_IO; use Ada.Text_IO;
with Ada.Numerics; use Ada.Numerics;
with Ada.Numerics.Complex_Types;
use Ada.Numerics.Complex_Types;

with Ada.Numerics.Complex_Elementary_Functions;
use Ada.Numerics.Complex_Elementary_Functions;

with Ada.Text_IO.Complex_IO;

procedure Show_Elem_Math is

package C_IO is new
   Ada.Text_IO.Complex_IO (Complex_Types);
use C_IO;

X, Y : Complex;
R, Th : Float;
begin
X := (2.0, -1.0);
Y := (3.0, 4.0);
Put (X);
Put (" * ");
Put (Y);
Put (" is ");
Put (X * Y);
New_Line;

R := 3.0;
Th := Pi / 2.0;
X := Compose_From_Polar (R, Th);
-- Alternatively:
-- X := R * Exp ((0.0, Th));
-- X := R * e ** Complex'(0.0, Th);

Put ("Polar form: 
   & Float'Image (R) & " * e**(i * 
   & Float'Image (Th) & ");
New_Line;

Put ("Modulus of ");
Put (X);
Put (" is ");
Put (Float'Image (abs (X)));
New_Line;

Put ("Argument of ");
Put (X);
Put (" is ");
Put (Float'Image (Argument (X)));
New_Line;

Put ("Sqrt of ");
Put (X);
Put (" is ");
Put (Sqrt (X));
New_Line;
end Show_Elem_Math;
Introduction to Ada

Project: Courses.Intro_To_Ada.Standard_Library.Show_Elem_Math
MD5: 24fd48ab69aeac28286e6ec8065899c5

Runtime output

(2.00000E+00, -1.00000E+00) * (3.00000E+00, 4.00000E+00) is (1.00000E+01, 5.00000E+00)

Polar form: 3.00000E+00 * e**(i * 1.57080E+00)
Modulus of (-1.31134E-07, 3.00000E+00) is 3.00000E+00
Argument of (-1.31134E-07, 3.00000E+00) is 1.57080E+00
Sqrt of (-1.31134E-07, 3.00000E+00) is (1.22474E+00, 1.22474E+00)

As we can see from this example, all the common operators, such as * and +, are available for complex types. You also have typical operations on complex numbers, such as Argument and Exp. In addition to initializing complex numbers in the cartesian form using aggregates, you can do so from the polar form by calling the Compose_From_Polar function.

The Ada.Numerics.Complex_Types and Ada.Numerics.Complex_Elementary_Functions packages provide operations for the Float type. Similar packages are available for Long_Float and Long_Long_Float types. In addition, the Ada.Numerics.Generic_Complex_Types and Ada.Numerics.Generic_Complex_Elementary_Functions packages are generic versions that you can instantiate for custom or pre-defined floating-point types. For example:

```ada
with Ada.Numerics.Generic_Complex_Types;
with Ada.Numerics.Generic_Complex_Elementary_Functions;
with Ada.Text_IO.Complex_IO;
procedure Show_Elem_Math is
 package Complex_Types is new Ada.Numerics.Generic_Complex_Types (Float);
 use Complex_Types;

 package Elementary_Functions is new Ada.Numerics.Generic_Complex_Elementary_Functions (Complex_Types);
 use Elementary_Functions;

 package C_IO is new Ada.Text_IO.Complex_IO (Complex_Types);
 use C_IO;
 X, Y : Complex;
 R, Th : Float;
```

23.4 Vector and Matrix Manipulation

The Ada.Numerics.Real_Arrays package provides support for vectors and matrices. It includes common matrix operations such as inverse, determinant, eigenvalues in addition to simpler operators such as matrix addition and multiplication. You can declare vectors and matrices using the Real_Vector and Real_Matrix types, respectively.

The following example uses some of the operations from the Ada.Numerics.Real_Arrays package:
with Ada.Text_IO; use Ada.Text_IO;

with Ada.Numerics.Real_Arrays;
use Ada.Numerics.Real_Arrays;

procedure Show_Matrix is

  procedure Put_Vector (V : Real_Vector) is
  begin
    Put (" (");
    for I in V'Range loop
      Put (Float'Image (V (I)) & " ");
    end loop;
    Put_Line (")");
  end Put_Vector;

  procedure Put_Matrix (M : Real_Matrix) is
  begin
    for I in M'Range (1) loop
      for J in M'Range (2) loop
        Put (Float'Image (M (I, J)) & " ");
      end loop;
      Put_Line (")");
    end loop;
  end Put_Matrix;

V1 : Real_Vector := (1.0, 3.0);
V2 : Real_Vector := (75.0, 11.0);
M1 : Real_Matrix :=
((1.0, 5.0, 1.0),
 (2.0, 2.0, 1.0));
M2 : Real_Matrix :=
((31.0, 11.0, 10.0),
 (34.0, 16.0, 11.0),
 (32.0, 12.0, 10.0),
 (31.0, 13.0, 10.0));
M3 : Real_Matrix :=
((1.0, 2.0),
 (2.0, 3.0));

begin
  Put_Line ("V1");
  Put_Vector (V1);
  Put_Line ("V2");
  Put_Vector (V2);
  Put_Line ("V1 * V2 =");
  Put_Line (" & Float'Image (V1 * V2));
  Put_Line ("V1 * V2 =");
  Put_Matrix (V1 * V2);
  New_Line;

  Put_Line ("M1");
  Put_Matrix (M1);
  Put_Line ("M2");
  Put_Matrix (M2);
  Put_Line ("M2 * Transpose(M1) =");
  Put_Matrix (M2 * Transpose (M1));
  New_Line;

(continues on next page)
```ada
Put_Line ("M3");
Put_Matrix (M3);
Put_Line ("Inverse (M3) =");
Put_Matrix (Inverse (M3));
Put_Line ("abs Inverse (M3) =");
Put_Matrix (abs Inverse (M3));
Put_Line ("Determinant (M3) =");
Put_Line (" ");
& Float'Image (Determinant (M3)));
Put_Line ("Solve (M3, V1) =");
Put_Vector (Solve (M3, V1));
Put_Line ("Eigenvalues (M3) =");
Put_Vector (Eigenvalues (M3));
New_Line;
end Show_Matrix;
```

**Runtime output**

V1
( 1.00000E+00 3.00000E+00 )
V2
( 7.50000E+01 1.10000E+01 )
V1 * V2 =
 1.08000E+02
V1 * V2 =
( 7.50000E+01 1.10000E+01 )
( 2.25000E+02 3.30000E+01 )
M1
( 1.00000E+00 5.00000E+00 1.00000E+00 )
( 2.00000E+00 2.00000E+00 1.00000E+00 )
M2
( 3.10000E+01 1.10000E+01 1.00000E+01 )
( 3.40000E+01 1.60000E+01 1.10000E+01 )
( 3.20000E+01 1.20000E+01 1.00000E+01 )
( 3.10000E+01 1.30000E+01 1.00000E+01 )
M2 * Transpose(M1) =
( 9.60000E+01 9.40000E+01 )
( 1.25000E+02 1.11000E+02 )
( 1.02000E+02 9.80000E+01 )
( 1.06000E+02 9.80000E+01 )
M3
( 1.00000E+00 2.00000E+00 )
( 2.00000E+00 3.00000E+00 )
Inverse (M3) =
(-3.00000E+00 2.00000E+00 )
( 2.00000E+00 -1.00000E+00 )
abs Inverse (M3) =
( 3.00000E+00 2.00000E+00 )
( 2.00000E+00 1.00000E+00 )
Determinant (M3) =
-1.00000E+00
Solve (M3, V1) =
( 3.00000E+00 -1.00000E+00 )
Eigenvalues (M3) =
```
Matrix dimensions are automatically determined from the aggregate used for initialization when you don’t specify them. You can, however, also use explicit ranges. For example:

```ada
M1 : Real_Matrix (1..2, 1..3) :=
    ((1.0, 5.0, 1.0),
    (2.0, 2.0, 1.0));
```

The Ada.Numerics.Real_Arrays package implements operations for the `Float` type. Similar packages are available for `Long_Float` and `Long_Long_Float` types. In addition, the Ada.Numerics.Generic_Real_Arrays package is a generic version that you can instantiate with custom floating-point types. For example, the Real_Arrays package can be defined as follows:

```ada
package Real_Arrays is new
    Ada.Numerics.Generic_Real_Arrays (Float);
```
### 24.1 Appendix A: Generic Formal Types

The following tables contain examples of available formal types for generics:

<table>
<thead>
<tr>
<th>Formal type</th>
<th>Actual type</th>
</tr>

<td></td>
</tr>
</tbody>
</table>
24.1.1 Indefinite version

Many of the examples above can be used for formal indefinite types:

<table>
<thead>
<tr>
<th>Formal type</th>
<th>Actual type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indefinite incomplete type</td>
<td>Any type</td>
</tr>
<tr>
<td>Indefinite nonlimited private type</td>
<td>Any nonlimited type indefinite or definite</td>
</tr>
<tr>
<td>Indefinite limited private type</td>
<td>Any type, limited or not, indefinite or definite</td>
</tr>
<tr>
<td>Incomplete indefinite tagged private type</td>
<td>Any concrete tagged type, indefinite or definite</td>
</tr>
<tr>
<td>Indefinite tagged private type</td>
<td>Any concrete, nonlimited tagged type, indefinite or definite</td>
</tr>
<tr>
<td>Indefinite tagged limited private type</td>
<td>Any concrete tagged type, limited or not, indefinite or definite</td>
</tr>
<tr>
<td>Indefinite abstract tagged private type</td>
<td>Any nonlimited tagged type, indefinite or definite, abstract or concrete</td>
</tr>
<tr>
<td>Indefinite abstract tagged limited private type</td>
<td>Any tagged type, limited or not, indefinite or definite abstract or concrete</td>
</tr>
<tr>
<td>Indefinite derived tagged type</td>
<td>Any tagged type derived from base type B, indefinite or definite</td>
</tr>
<tr>
<td>Indefinite abstract derived tagged type</td>
<td>Any tagged type derived from base type B, indefinite or definite abstract or concrete</td>
</tr>
</tbody>
</table>

The same examples could also contain discriminants. In this case, (<>), is replaced by a list of discriminants, e.g.: (D: DT).

24.2 Appendix B: Containers

The following table shows all containers available in Ada, including their versions (standard, bounded, unbounded, indefinite):

<table>
<thead>
<tr>
<th>Category</th>
<th>Container</th>
<th>Std</th>
<th>Bounded</th>
<th>Unbounded</th>
<th>Indefinite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vector</td>
<td>Vectors</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>List</td>
<td>Doubly Linked Lists</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>Map</td>
<td>Hashed Maps</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>Map</td>
<td>Ordered Maps</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>Set</td>
<td>Hashed Sets</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>Set</td>
<td>Ordered Sets</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>Tree</td>
<td>Multiway Trees</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td>Y</td>
</tr>
<tr>

<td></td>
<td></td>
<td></td>
<td>Y</td>
</tr>
<tr>
<td>Queue</td>
<td>Synchronized Queue Interfaces</td>
<td>Y</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Queue</td>
<td>Synchronized Queues</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Queue</td>
<td>Priority Queues</td>
<td>Y</td>
<td>Y</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Introduction to Ada

Note: To get the correct container name, replace the whitespace by _ in the names above. (For example, Hashed Maps becomes Hashed_Maps.)

The following table presents the prefixing applied to the container name that depends on its version. As indicated in the table, the standard version does not have a prefix associated with it.

<table>
<thead>
<tr>
<th>Version</th>
<th>Naming prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td>Std</td>
<td></td>
</tr>
<tr>
<td>Bounded</td>
<td>Bounded_</td>
</tr>
<tr>
<td>Unbounded</td>
<td>Unbounded_</td>
</tr>
<tr>
<td>Indefinite</td>
<td>Indefinite_</td>
</tr>
</tbody>
</table>
